Barbarism is often charged, with great justice, on modern writers in the learned languages. The Latin books of late ages are full of Anglicisms, Gallicisms, Germanisms, &c. according to the country of the author. But what shall we say of such, as, 1 Corinthians, who accuses Cicero himself of barbarisms in his own language?

There are great disputes among critics concerning barbarisms in the New Testament.

Divers pious persons are startled at the apprehension of any thing like a barbarism in the inspired books, as supposing it an objection to the inspiration of them; yet this does not hinder but many of the Jews, after Abarbanel and others, still maintain barbarisms in the Old Testament; in which they are fecnded by M. Simon, Le Clerc, and others. The latter of these writings abound with Zaldastins; and the books of Moles are not free from Egyptian words.

If we consider that among native Greeks a barbarous idiom could only mean such as was not conformable to the rules of their grammarians and rhetoricians, and to the practice of their writers of reputation, it may be conceded that the style of the New Testament is of this kind, without derogating from the character of the apostles and evangelists, without impeaching their inspiration, and without injuring the authenticity of their writings. This conception, the most learned and oratorical of the Greek fathers, as for instance Origen and Chrysostom, did not scruple to make: and, in such cases, it must be acknowledged that a native of common fens is a much better judge than any learned foreigner. Nevertheless many have contended that the Greek of the New Testament is as purely classical as that of the Attic writers, and they have even condemned as impious rhetorics those who have dared to differ. It has been asserted, that the contrary implies an imperfection inconsistent with divine inspiration, and that men capable of such a doctrine were not only impious, but were guilty of the sin against the Holy Ghost. And yet this doctrine was maintained by Erasmus, Calvin, Melanthon, Camerarius, Beza, Drefitus, Catenon, Gaffius, Gatakes, Solanas, Olearius, and Vor- flius; though it has been denied by Ptochianus, Stolberg, Schmid, Georgi, and Blackwall. See Erneli Instituio Interpretis N. T. p. 41. ed. 31a. Lipfex, 1775. But the advocates for this divine purity have not only betrayed their ignorance of the Greek language, but a high degree of pedantry in estimating the accuracy of language beyond its proper value. This last mistake has happened not only to the warm and partial friends, but likewise to the enemies of Christianity, who, from the time of Celsus to the 18th century, have maintained, that a book written in such language is neither divinely inspired, nor deserving attention and respect. Both parties have carried their zeal and their sentiments to too great a length; and they would hardly consider an absolute purity of style, and a total absence of foreign words, of such importance as to make the contrary a crime, if they would confende to quit the language of the schools for that of common life, or turn their attention from the language of the chaff to the wheat that are in common use. All foreign idioms, such as Hebraisms in Greek, Grecisms in Hebrew, or Latinisms in either, may be comprehended within the definition of barbarism, and sometimes even of fossilism; but these words, it should be recollected, have always something relative in their signification; that turn of expression being a barbarism or fossilism in one language, which is strictly proper in another, and to one class of hearers which is not so to another. The apostle Paul does not hesitate, by implication, to call every tongue barbarous to those who do not understand it. 1 Cor. xiv. 11. Nor does it make any difference, as appears from the whole of the apostle's argument, even if what is spoken be spoken by the Spirit. With equal reason we may say of those foreign idioms in any tongue, which render what is said unintelligible or even obscure to the natives, that in respect of them they are barbarisms. Nor will any judicious person deny, that there are some idiomatical expressions in the New Testament, which must have puzzled those who were absolute strangers to the language of holy writ. Such idioms the writers of the New Testament would naturally adopt. They occurred in the Septuagint, which they were in the habit of using; and these would co-operate towards infecting their style with the tendency, which, as natives of Palestine, they would derive from conversation, to intermix Hebraisms and Chaldaisms in their writings. If we would enter thoroughly into the idiom of the New Testament, we must familiarize ourselves with that of the LXX; and if we would enter thoroughly into the idiom of the LXX, we must accustom ourselves to the study, not only of the original of the Old Testament, but of the dialect spoken in Palestine between the return of the Jews from the Babylonish captivity and the destruction of Jerusalem by the Romans; for this last, as well as the Hebrew, has affected the language both of the old Greek translation and of the New Testament.

Besides, it is proper to consider in relation to this subject, that vulgarisms and foreign idioms, which may obtain among strangers, and those of the lower ranks, have no more natural unifomes to convey the ideas which they use than intend to convey by them, the terms and phrases which, in consequence of the preference given by their superiors, may be regarded as elegancies. It may be as reasonably objected against our religion, that the persons by whom it was propagated were chosen from a class which men in high life account the dregs of the people, as that the Holy Spirit should accommodate himself to the language of those who were actually chosen. Nay, language as well as deeds being in fact no more than a species of mode, it may with as good reason be maintained that the ambassadors whom Christ deputed to promulgate his doctrine, should have been habituated like gentlemen and men of fashion, as that they should have spoken the dialect of fuch. Should it be asked, why did the Holy Spirit chuse to deliver such important truths in the barbarous idiom of a few obscure Galileans, and not in the polite and more harmonious strains of Grecian eloquence? The answer is obvious:—That it might appear beyond contradiction, that the excellency of the power was of God, and not of man. Moreover, the writings of the New Testament carry, in the very exprefion and idiom, an intrinsic and irrefutable evidence of their authenticity. They are such as, in respect of style, could not have been written but
BAR

by Jews, and hardly even by Jews superior in rank and education to those whose names they bear; and the argument is strengthened by considering that under their voluntary garb we find the most exalted sentiments, the closest reasoning, the purest morality, and the profoundest doctrine. In the diffusion of this subject, we should likewise consider the situation and character of the persons for whose benefit the New Testament was more immediately written. They were mostly either native Jews, or pious persons who were professedly to the doctrine of Moses, and who, by continual intercourse with native Jews, and the constant reading of the LXX., were accustomed to Jewish Greek. It is highly probable therefore, that if the New Testament had been written with Attic purity, it would have been unintelligible to many of its earlier readers, who had never read the doctrines of religion in any other dialect than Jewish Greek. We shall only observe further in this place, that a classical or uncritical style has no more influence on the divinity of the New Testament, than the elegance or inaccuracy of the hand in which it is written, and the accuracy or inaccuracy of the pronunciation with which it is uttered. Whoever is accustomed to write a bad hand would certainly not improve it by his inspiration, but admitting there, it would have this unfortunate consequence, that no one accustomed to the hand would in its improved state believe it to be genuine. There is no reason to believe, that inspiration would amend a faulty pronunciation; and the writers of the different parts of the Bible have undoubtedly spoken in the same manner, both before and after the effusions of the Holy Ghost. If these failings then are consistent with supernatural endowments, “I can see no reason,” says Michaelis, “for drawing an argument against the divinity of the New Testament from its vulgarisms, or even from its grammatical errors.” A particular account of the writings of those authors, who have engaged in the controversy relating to the purity of the language of the New Testament, may be seen in Walchii Bibliotheca Thologica, t. iv. p. 270—289; See also Fabr. Bibl. Græc. t. iv. p. 224—227. Michaelis’s paper on the Introduction to the New Testament by Mark, vol. i. ch. 4. 34. p. 116, &c. Campbell on the Four Gospels. Prelim. Diff. vol. i. p. 13, &c. See more on this subject under the articles Inpiration, and Language of the New Testament.

BARBARISM, Barbaries, is also used for that rudeness of mind, wherein the understanding is neither furnished with useful principles, nor the will with good inclinations. BARBARISSOS, in Ancient Geography, a town of Asia, in Syria, in the Chalybonntie country. Ptolemy.

BARBARIUM Promotorium, a promontory of Sutherland, placed by Ptolemy south of the city of Omos-Hippon, or Oloepion, Oléope, or Libon, in 39° 45 N. latitude.

BARBARO, Francis, in Biography, a noble and learned Venetian, was born in 1508, and distinguished by his love of literature, and his talents for public business. Under the learned Greek Chrysologus, he acquired that profound knowledge both of the Greek and Latin languages, of which he gave specious in his translutions of Plutarch’s lives, of Aristides, and Cato, and in his elegant moral work, written in Latin, intitled “De Re Uxoria,” and first published without his name, in 450. at Paris, in 1515. This work furnishes useful instructions with regard to the choice of a wife, and the duties of wives and mothers. He was also the author of some orations and letters, which manifested good taste and an amiable temper. In all the public offices which Barbaro fulfilled, he displayed eminent virtues. Whilst he was governor of Brescia, he had occasion for the exercise both of courage and discretion. The city was divided into two violent factions, which he prevailed upon to unite, and to act in concert for the public good; and though at the same time it was besieged by the Milanese forces under the great commander Piccinino, and suffered much by famine and disease, he at length, after a protracted siege of three years, obliged the enemy to retire. He died which regretted by his countrymen, in 1554, at the age of fifty-six years. His letters were collected and printed at Brescia in 1743. (Gen. Dict.)

BARBARO, Ernolao, the elder, was the nephew of the preceding, and distinguished by his early acquaintance with the Greek language, inasmuch that at twenty years of age he translated many of Alop’s fables into Latin. He was advanced, at the age of thirty years, by pope Eugenius IV. to the episcopal see of Treviglist; and ten years afterwards he was translated to that of Verona, where he died in 1470, aged sixty years. He left translatons of Greek authors.

BARBARO, Ernolao, of Hermolaus Barbarus, the younger, was the grandson of Francis Barbaro, and born at Venice, in the year 1554. In very early life he was eminently distinguished by his genius, application, and piety; and at the age of fourteen years he received from the hand of emperor Frederic the poetic crown. At sixteen, he undertook the translation of Themistius, which was published seven years afterwards. Having graduated in the school of Padua in jurisprudence and philosophy, he returned to Venice, and devoted himself entirely to affairs of state. However, after an interval of twelve years, he returned his studies with fresh ardour; and, particularly attached to the Greek language, he read lectures without gratuity, in his own house, upon Demochines, Theocritus, and Aristotle, which were very numerously attended. At the age of thirty-two years, he was sent ambassador to the emperor Frederic, who conferred upon him the honour of knighthood; and in consequence of a subsequent embassy to pope Innocent VIII. that pontiff created him patriarch of Aquileia. This office he accepted, though the laws of Venice had prohibited its ministers from accepting any dignity from any foreign prince, without the consent of the republic; and for his opposition to this order, the Venetians pronounced upon him a sentence of perpetual exile. For preventing his execution he wished to relinquish the patriarchate; but the pope refused to accept the renunciation. From this time, he retired at Rome; but upon the access of the plague, he returned into the country, which, however, afforded him no asylum; for he was seized with this malady, and died in the year 1493.

Betrudes the translation of Themistius, Hermolaus published versions of Dioecides, and of the rhetoric of Aristotle, an abridgment of the moral and physical doctrine of that philosopher; two large works upon Pliny, one intitled “Constitutions Pliniae,” the other “Constitutions Secundo”; “Corrections of Pomponius Mela;” and an “Explanation of the more difficult words in Pliny.” He boasted that he had corrected 5000 errors in the text of Pliny, and 300 in that of Mela. Although he is charged with having been too free in his conjectural emendations, he exercised great ingenuity and industry in these labours. The illustrious Lorenzo de’ Medici treated him with great respect, and when he was at Florence on an embassy from the republic of Venice, entertained him very liberally, and offered him the use of his villa and library to the prosecution of his studies. “Hermolaus is certainly entitled to rank in the first clays of learned men, at a period when classical learning was the first and almost the sole object of attention: nor is it any depreciation of his merit as a scholar, whatever it may be of his character as a philo-

BAR
phes, if the whimsical story he be true, that, being exceedingly perplexed concerning the meaning of Ariketo's book, a term which has perhaps never been understood, he endeavoured, or pretended to consult the devil upon the subject." Gefner in Bibliothec. Gen. Dict.

BARBAROSSA, so called from the red colour of their beard, Arie or Horace, and Hayradin, were the sons of a potter of the island of Lefbos, or some fay, of a Sicilian renegado; who, by the advice of reftles and enterprising spirit, forsook their father's trade, and joined a crew of pirates. They soon distinguished themselves by their valour and activity, and becoming masters of a small brigantine, carried on their infamous trade with such conduct and success, that they assembled a fleet of twelve galleys, besides many vessels of smaller force. Of this fleet, Horace, the elder brother, was admiral, and Hayradin second in command, but with almost equal authority. They called themselves the friends of the sea, and the enemies of all who fall upon it; and their names soon became terrible to the frights of the Dardanelles to those of Gibraltar. Whilft they were acting as Corsairs, they adopted the ideas and acquired the talents of conquerors. They often carried the prizes which they took on the coasts of Spain and Italy, to which they extended their depredations about the year 1524, into the ports of Barbary; and enriching the inhabitants by the sale of their booty, and the thoughtless prodigality of their crews, they were welcome guests in every place at which they touched. The convenient situation of these harbours, lying near to the greatest commercial states at that time in Christendom, made the brothers with for an establishment in that country. An opportunity occurred for this purpose, which they eagerly seized and improved to their own advantage. Eutemis, king of Algiers, having made several unsuccessful attempts for taking a fort which the Spanish governors of Oran had built not far from his capital, fought the assistance of Horace, whose valour the Africans considered as irresistible. The active corsair gladly accepted the invitation, and leaving his brother Hayradin with the fleet, marched at the head of 5000 men to Algiers, where, in the year 1516, he was received as their deliverer. Such a force gave him the command of the town. The ambitious conqueror, having secretly murdered the monarch whom he came to assiil, caused himself to be proclaimed king of Algiers in his stead. He then proceeded to establish the authority which he had usurped, by acts suited to the genius of the people whom he had to govern; by unbounded liberality to those who favoured his promotion; and by cruelty as unbounded towards all whom he had any reason to distrust. Having detected and defeated a conspiracy formed against him by the Arabs, and obliged the king of Tunis, who marched to their succour with a powerful army into the territory of Algiers, to seek refuge in the mountains; Barbarossa laid siege to Tunis, made himself master of it, and was acknowledged as sovereign. He then attacked the neighbouring town of Tremecen, vanquished him in battle, and added his dominions to those of Algiers. At the same time he continued his depredations on the coast of Spain and Italy; and the devastations which he committed obliged Charles V., at the beginning of his reign, to furnish the marquis de Comares, governor of Oran, with troops sufficient to attack him. That officer, affiiald by the dethroned king of Tremecen, executed the commination of such spirit and success, that Barbarossa's troops being defeated in several encounters, he himself was shut up in the citadel of Tremecen. After defending it to the last extremity, he was reduced by the apprehension of famine to the necessity of attempting an escape by a subterranean passage; and in order to delay the pursuit, he scattered his treasures upon the road. At length the Spaniards overtook him on the banks of the Ilissus, eight leagues from Tremecen; and here Barbarossa with his Turkísh followers fought for some time with an obstinate valour, but they were at last totally defeated, and the conqueror himself was slain, in the forty-fourth year of his age, A.D. 1518.

His brother Hayradin, known likewise by the name of Barbarossa, assumed the sceptre of Algiers with the same ambition and abilities, but with better fortune. His reign being undisturbed by the Spaniards, who were fully engaged in the wars among the European powers, he regulated with admirable prudence the interior police of his kingdom, carried on his naval operations with great vigour, and extended his conquests on the continent of Africa. For his greater security, he put his dominions under the protection of the Grand Signior, and received from him a body of Turkísh soldiers sufficient for his defence against domestic as well as foreign enemies. Solymans at length A.D. 1553, offered him the command of the Turkísh fleet in opposition to Andrew Doria, who was the greatest seafarier of that age. Barbarossa, proud of this distinction, repaired to Constanffupole, and with a wonderful versatility of mind, combined the addresses of a courtier with the boldness of a corsair, and thus gained the entire confidence of the sultan and his vizier. To them he communicated a scheme which he had formed of making himself master of Tunis, the most flourishing kingdom, at that time, on the coast of Africa; and as they approved the scheme, they furnished him with everything he demanded for carrying it into execution. Avoiding himself of the intertinted divisions of the kingdom, and making pernicious use of the name and interest of Abrahichid, an exiled prince, whom he deceived and imprisoned, he was supported by a powerful fleet and a numerous army. His fleet consisted of 250 vessels, with which he fell towards Africa; and after ravaging the coasts of Italy, he appeared before Tunis. Having landed his men, he announced his intention of affording the right of Abrahichid, whom he pretended to have left sick on board of the admiral galleys, but who was in reality confined in the seragli at Constantinople, and who was never heard of more. The fort of Golosta, which guards the bay, soon submitted, and the inhabitants of Tunis declared unanimously in favour of Abrahichid; so that the gates were open to Barbarossa, whom they considered as the restorer of their lawful sovereign. But as Abrahichid did not appear, they soon began to suspect their corsair's treachery; and with arms in their hands, surrounded the citadel into which Barbarossa had led his troops. Their attack, however ardent and impetuous, was of no avail; and they were forced to acknowledge Solymans as their sovereign, and to submit to himself as his viceroy. Having put the kingdom into a proper posture of defence, he extended his depredations to the Christian states, so that complaints of his outrages were conveyed to the emperor Charles by his subjects both in Spain and Italy. The emperor concluded a treaty with Muley-Hafcen, the exiled king of Tunis, who implored his assistance; and made preparations for invading Tunis. His fleet consisted of nearly 500 vessels, and they had on board above 30,000 regular troops. The armament failed from Cagliari, and after a prosperous navigation, landed within sight of Tunis. Barbarossa assembled at Tunis for opposing the imperial army.

Vol. III.
force, a force composed of 20,000 horse, together with a
cavalry body of foot. By the reduction of the Genoese, after
an obstinate defence by the Turkish soldiers under the
command of Sinan, a renegade Jew, the bravest and most
experienced of all Barbarossa's corsairs, the emperor became
master of the fleet, confining of eighty-seven galleys and
galliots, together with the arquebus, and 300 cannon mostly
of brass, that were planted on the ramparts. In these
circumstances, however, Barbarossa, neither lost his courage,
nor abandoned the defence of Tunis. But as the walls were
extremely weak as well as extensive, he determined to
advance with his army, amounting to 50,000 men,
towards the imperial camp, and to decide the fate of his
kingdom by the issue of a battle. Having communicated
his resolution to his principal officers, he proposed to provide
against the danger of a mutiny among the Christian slaves,
during the absence of the army, by massacring 10,000 of
them before he began his march. The barbarity of the
proposal filled his officers with horror; and Barbarossa,
dreading their resentment, contented to spare the lives of
the slaves. The emperor's army which suffered inconceivable
hardships in their march over burning sands, soon
came up with the Moors and Arabs under the command of
Barbarossa, who were so completely routed, that, notwithstanding
all his efforts to rally them, he was hurried along
with them in their flight back to the city. This was found
a scene of confusion; some of the inhabitants were flying
with their families and effects; others were opening
the gates to the conquerors; and the Turks were retreating;
and the citadel was in possession of the Christian slaves.
Barbarossa, disappoinited and enraged, fled precipitously
to Bone; and Tunis surrendered to the victorious army of the
emperor. But the squire of this victory was tarnished by the
excesses of the soldiers: who sacrificed more than 30,000
of the innocent inhabitants, and carried away 10,000 of them
as slaves. Barbarossa escaped first to Algiers, and then
repaired to Constantinople, where he was received again
into favour, and sent with a fleet to ravage Calabria. Having
persuaded Solymans to make war on the Venetians, he
committed great devastations in the isle of Corfu, and afterwards
made an expedition to the coast of Arabia Felix,
when he reduced all Yemen under the Turkish dominion.
In a subsequent war between the Turks and Venetians, he
took many islands in the Archipelago. In 1538 he crossed
over to Candia, and made an unsuccessful attempt on
Canea. From thence he retired to the Ambracian gulf,
where he was overtaken by the Christian fleet under the
famous Andrew Doria. By his skilful maneuvres he not
only avoided the danger that threatened him, but gained
some partial advantages, and caused Doria to make a hasty
retreat to Corfu. In 1539 he recovered Caffo Nuovo
from the confederates. In 1542, Barbarossa left Constantinople
with a powerful fleet; and proceeding to the Faro
of Messina, took Reggio, and sacked the coast of Italy.
He then besieged and took Nice; but when Doria
approached with his fleet, Barbarossa avoided him; and
remaining in those quarters during winter, he next spring ravaged
the coasts and islands of Italy, and then returned with
many prisoners to Constantinople. During the remaining
period of his life, he superintended the naval affairs of
the grand signor, and perused that voluptuous course
to which he had been habituated, amidst a number of fair
captives; and died at the age of eighty years, in 1547,
leaving his son Hassan in possession of the vicereignty
of Algiers, and heir to all his property. With the ferocity of
a Turk and Corsair, Barbarossa pillaged some generous
sentiments, and obtained a character for honour and fidelity

Barbarossa, in Entomology, a species of Scarabaeus,
described by Fabricius as a native of New Holland. The
anterior part of the thorax is fucarous; horns of the head
receded and short.

BARBAROUS, in a general sense, denotes something
that partakes of the quality of Barbarism: and in this
sense, the term is applied to a nation, age, writer, word,
or the like. Barbarous Latin words are innumerable;
the schoolmen abound with them; the chemists, physicians,
and lawyers can scarcely write intelligibly without them.
Du Cange has given two large volumes in folio of barba-
rous Latin words, and as many of barbarous Greek words.
The modern or vulgar Greek is sometimes called barbarous
Greek, "barbaro-Greca," or "Greco-barbaro lingua." Langius has published "Philologin Barbaro-Greca," "Gram-
matica Barbaro-Greca," or "Glossarium Barbaro-Grecum."

Barbarus, in Entomology, a species of Papilio. (Pllb. Kur.) The wings are without tails, and blueish;
beneath spotted all over with brown, and two spots behind.

Barbarus, a species of Tenbriggs, of a black colour,
and very glossy; thorax orbiculated; anterior margin of
the shield of the head elevated. This is about the middle

Barbarus, a species of Cryptoccephalus that inha-
bits Barbary. The antennae are serrated: body hairy,
black or brown, found on composite flowers. Fabricius.

Barbarus, in Ichthyology, a species of Synagnathus,
found in European seas. It has neither caudal nor anal
fin, body fuscolated. Gmelin. In the dorsal fin are about
forty-three rays; and in the pectoral fin ten rays; body
olive with faint blueish transverse lines.

Barbarus, in Ornithology, a species of Vulgar that
inhabits Barbary, and some other parts of Africa. It is of
a blackish brown; beneath white, inclining to brown;
legs woolly; toes head colour; claws brown. Gmelin.
This is vulgar barbatus, Brull. Orn. and bearded vulture
of Edwards and Latham.

Barbarus, a species of Falco, called by the English
writers Barbary falcon; the cere and legs are yellowish;
body blueish, spotted with brown; beak immaculate.
Tail banded. Gmelin. The length of the bird is seventeen
inches, and, as its name implies, it is a native of Bar-
bar.

Barbarus, in Geography, the northern tract of Africa,
is one of the three distinct parts of North Africa, accord-
ing to the distribution of major Rennel, and lying along the
Mediterranean. See Africa.

As to the origin of the name of Barbary, we have a
variety of conjectures. Some suppose, that the Romans
after they had conquered this large tract, gave it the name
by which of contempt or dislike of the rude and barbarous
manners of the natives. Marmol deduces it from the
Arabic word "Barber," a name given by the Arabs to the
ancient inhabitants, and which they retain to this day in
many parts of this tract, especially along the ridge of the
Great Atlas, where they are very numerous, and which was
given to them by their new invaders on account of the bar-
barisms of their country. Leo Africanus says that it was
given to these people on account of their strange language,
which appeared to them an inarticulate murmur, the Arabic
word "barbar," signifying "a murmuring sound or noise."
Barbary derive it from "barb," once repeated [sic], which signifies a "desert," which was its ancient name; accordingly, they say that the fugitive king Ithik, from whom it is pretended that the whole African continent derived its name, when closely pursued by his enemies in his flight out of Arabia Felix, and halting what course to pursue, was directed by none of his retainers by these words, "Bar, Bar," that is "To the Desert." To the Desert.
ichoeneumon or tezerde; the frett or nimfe; and the weefel
or fett-el-heile. The mole, likewise, the rabbit, the hare,
and the wild boar, which is the chief prey and food of
the hons, are every where numerous. Among the oviparous
quadrupeds, Dr. Shaw enumerates the land and water tor-
toises, the former being very palatable food, but the latter un-
whollyome; the warral or guara; the dhah or daf; the zem-
mounah; the flink or femeus; and the neje-daimah or
booka-flain. Of the ferpentine kind, besides the flow-sworn
and the snake, which are common, the moft remarkable spe-
cies are the thabanne, the zurweike or jucule, the leffiah or
difpas. These are the only species of the viper kind which
Dr. Shaw discovered; and he adds, that the northern parts of
Africa do not produce above five or fix diflinct species among
the many that are decribed by Lucan and Nicander.
Among the birds, he enumerates, besides the eagle kind, the
karbunro, about the fize of our buzzard, the red-legged
crow, or pyrrhocor; the emfeefy or ox bird; the boof-unk
or long-neck; the burou-rou, one of the larger fpecies of the
horned-owls; the varourou; the fhamarg; the houbarra or
houbaary; the rhand or fat-fat; the kitawiah or African
lagopus; the Barbary parachute, or red-legged quail; the
green thrush; and the Capia fparrow. The infects of this
part of Africa are more numerous than curious. The moft
curious fpecies of the butterfly kind is the lappet butterfly,
about four inches from one tip of the wing to the other,
beautifully flecked with murrey and yellow, and having
near the tail a fpot of a carafion colour. The rareft fpecies
of the libell or adderbolts is one, 55 in his long, broad-
tailed, of a ruby colour, with bright fpotted wings. The
leaffent of the beetle kind, is a fpecies with one horn,
of the colour and fize of a chefunt. In the hotter months
of the fummer, the cicade, 714. § or gralfhopper, as we falfely
translate it, is perpetually flamings the ears with its flirli
and ungrateful noffe, from mid-day, to the middle of the after-
noon. The locufs are very numerous, first appearing to-
wards the latter end of March, and in the middle of April
forming large fwarmes, which even darken the fun, and
beginning gradually to disappear in May. Of the acrab or
fcorpion there are feveral fpecies. For other particulars
relating to the productions, commerce, cuftoms, &c. of the
flates of Barbary: See Algiuers, Morocco, &c.

The coal of Barbary was probably firft planted by the
Egyptians. The Phoricians afterwards fer fent colonies thither,
and built Utica and Carthage. The Carthaginians from
then gave power and weathy by trade, and finding the country
divided into many little kingdoms and flates, either infiubed
or made the princes on that coal their tributaries, who,
being weary of their yoke, availed themselves of the oppor-
tunity of affifting the Romans in fubduing Carthage.
The Romans remained sovereigns of the coal of Barbary, which
indeed was almofl the whole of their poiffefion, Egypt ex-
cepted, on the continent of Africa, until the Vandals in the
fifth century reduced it under their dominion. The Roman,
or rather the Grecian emperors, having some time after
recovered the coal of Barbary from the Vandals, retained the
dominion of it till the Saracen califh made an entire conqul
of the north of Africa in the feventh century, and divided
the country among their chiefs, of whom the fovereign of
Morocco was the moft confiderable, poiffefling the north-west
part of that country, which, in the Roman division, obtained
the name of Mauritia Tangitania, or Tunis or Tar-
gier the capital; and is now flyled the empire of Morocco,
comprehending the kingdoms or provinces of Fez and Mo-
rocco.

In the eight century, their ancers made a con-
quell of the great part of Spain; but after the lofs of
Granada, about the year 1492, they were dispoiffefl of this
country, and compelled by Ferdinand and Isabella to re-
nounce their religion, or transport themselves to the coal of
Africa. The exiles confederated with the Mahometan
princes on the coal of Barbary, and fitted out little fleets
of cruisers, which made depredations on Spain, brought away
many of its inhabitants, and made flaves of them. The
Spaniards aflembled a fleet of men of war, invaded Barbary,
took Oran and other places on the coal of Algiers, and were
proceeding to make an entire conqul of the country. In this
difficulty the African princes bought the affilience of the
famous Turkih rover called Barbarossa (see the article Bar-
Barbary, sregard the Christians. When he had repulfed their
enemies, he unfurfed the government of Algiers, and treated
the people who called him to their faccour as flaves. His
brother Hayradin pursufr the fame fmeafures with regard to
the people of Tunis; and a third by fimilar means obtained
the government of Tripoli. In these aflurations they were
supported by the grand fignior, who claimed the fovereignty
of the whole coal, and for fome time they were confidered
as the fubjefts of Turkey, and governed by Turkih backaws
and viceroyes; but each of thefe flates, or rather the military
men, at length elected a fovereign out of their own body, and
rendered themselves independent of the Turkih empire.
The grand fignior has not now fo much as bafaw or officer
at Algiers; but the day acts as an absolute prince, and is
only liable to be depofed by the foldiery that advanced him.
At Tunis and Tripoli he has full bafaws, who are some
check upon the days, and receive a fmall tribute. All of
them, however, in cafe of emergency, claim the protection
of the Ottoman court; and they still continue to pray upon
the Spaniards, having never been at peace with them since the
lofs of Granada. They make price alfo of all other Chrifti-
fanfs hips that have Spanih goods or passengers on board, and
indeed of all others that are not at peace with them. The
Turks of Algiers, Tunis, and Tripoli, are an abandoned
race, conflifting of pirates, banditti, and the refufe of Turkey,
who have been forced to have their fccurities to avoid the
punifhment of their crimes. See Algiuers, &c. and
also Africa.

Barbary is chiefly inhabited by three forts of people ;
namely, Moors, who are the native natives; the Arabs,
who have overran this country; and the Turks, who have
fince made themfelves masters of fome of its belt provinces,
and the feveral kingdoms of Tripoli, Tunis, and Algiers,
being under a kind of tribute to, or dependence upon the
Ottoman porte. The Moors, or natives, are for the moft
part Mahometans; as there are few who have not been in-
duced or compelled to embrace Mahometanfimine their fub-
jection to the Turks. They are even more ferupulous ob-
servers of the Mahometan law than the Turks fhemselves;
and as they are generally even more ignorant, they have
adopted every absurdity of fuperfition. Among the cor-
fairs of Barbary, no charm, or magic spell, no expedient,
thoug hun to fome feelefs, monftrous, and feemingly diabolical,
can be invented, to which they will not have recourse,
preferably to any of a more rational nature and efficacy,
in fights, forms, or other emergencies attending their hazardous
profeflion. Their condition is abject and miferable to the
extreme, being cruifed with a heavy load of taxes, and
freated with the umoft cruelty by their infulting masters, or
expofed to the continual invads of the plundering Arabs.
Such is the flate of thofe who live at large in the country
upon their agriculture and cattle. As thofe who inhabit
the fea-ports along the coal, they are allowed to follow a
variety of handicraft trades and manufactures, and even to
carry on some commerce by land and sea. But they are no
lfs oppreffed with taxes and other exactions.
BAR

The Arabs of Barbary are like those of other parts of Africa; they follow the same mode of living, are governed by their own despotic checks, and all of them, except those of the wandering kind, and such as live under the domination of the emperors of Morocco and Fez, are in some sort tributary to the Turks, ever since they have made themselves masters of the remainder of the Barbary coast. They are often obliged, by the oppression they suffer, to abandon their habitations, and to seek shelter among the most rocky and inaccessible mountains, whether the Turkish forces cannot pursue them. Such is the condition of those who live in the country, and along the ridge of mount Atlas; but there is another and more civilised class of them, who are, like the Moors, settled in some of the towns and villages, and apply themselves to agriculture, and especially to the breeding of that race of horses so much esteemed, known to us by the name of barbs, for which their country has been famous all over Europe. The wild, or wandering Arabs, who range along the great Atlas and other parts of Barbary, are warlike, bold, and even desperate in all their plundering excursions; especially in their attempts on the large and rich caravans, which go from Morocco into Egypt. The Arabs of each class are addicted to the study of astronomy and astrology, to which they are disposed by their pastoral life, which affords much leisure, their clear sky, and natural superstition. They neither few reap, plant, travel, buy, or sell, nor undertake any expedition, without previously consulting the stars, or in other words, their almanacks, or some of the makers of them, whether they be Mahometans or idolators.

The Turks are of all the inhabitants of Barbary the fewest in number, and in all respects the worst of all the three classes; being originally no better than a wretched crew of indifferent, loose, idle, and thriftless fellows, infested in and about Constantinople, and sent from thence once in three years to recruit the foldiery. They are wanton and sanguine in the exercise of their tyranny over both the Moors and Arabs. They make ostentatious professions of Mahometanism; but in practice they neglect and violate its precepts in the most licentious degree, and are so notorious for the dissoluteness of their manners, that they are abhorred by all true Mahometans.

The whole tract of Barbary from one end to the other is so excellently situated for navigation and commerce, so fertile of every necessary of life in its variety of soils and climates, so rich in its mines of gold, silver, and other metals and minerals, so healthy, and so populous, that it might defy the whole force of Europe or Asia to reduce it, were its inhabitants as indolent as they are indolent and knavish, and were the several nations that inhabit it, or the several powers to which it is subjected, united in one common interest. Shaw's Travels, passim. Mod. Un. Hist. vol. xi. p. 256. &c. vol. xiv. p. 288. vol. xxxvii. p. 186. &c.

BARBARY Point, the western point of the entrance into the river, &c. of Senegal, on the coast of Africa. N. lat. 15° 38'. W. long. 15° 30'.

BARBAS, Cape, lies on the coast of Africa, west from Cyprino river, and 26 leagues north from cape Blanco. N. lat. 22° 15° 30'. W. long. 16° 20'.

BARBASOTE, a sea-port town of Africa, in the kingdom of Fez, a little to the west of Ceuta.

BARBASTELLUS, Avespertilio, in Zoology, the so-called bat, with elevated hairy cheeks, and large ears, angulated on the lower part. (Linn. Syst. Nat. Gmelin, p. 48.) Barbysilette of Buffon and Pennant. Its length is about two inches from nose to tail; extent about ten inches; 100 part of the body dusky-brown; under part ash-coloured; forehead fawn; ears broad and long, lower parts of the inner side touching each other, and thus concealing the face and head when viewed in front; nose short; cheeks full; end of the nose flattened; found in France. Shaw.

BARBATA, in Entomology, a species of CANTHARIS that inhabits Germany. It is of a brown colour; antennae and cheeks pitchy. Oliver. The down on the body is changeable to a golden hue.

BARBATA, a species of CICADA (Dysca) of a brown colour, with greenish abdomen, and a snowy-white woolly tuft at the vent. Fabreius, Gmelin.

BARBATA, a species of PHALÉNA that inhabits Barbary. The wings are greyish, with a brown spot in the middle, and an oblique band behind. Fabreius, &c.

BARBATA, a species of PIMELIA (Helops Fabr.), of a black colour; feathers advanced, and with the legs yellowish. Inhabits Saxony. Fabricius.

BARBATA, in Natural History, a species of CORALLINA, about three inches in length, that grows on the shores of Jamaica. Ellis, in his work on coralline, calls it the rotatory or head-coraline of Jamaica; it is the head-band of Flusknat, and corallina major, nerve craffieri fuciform intermedia bivertex necente of Swane. (Hist. Jam.) This kind is specifically distinguished according to Dallas, Solander, and others, by being dichotomous, with cylindrical joints, the extreme ones bearded at the tips.

BARBATA, a species of NAIS, about one third of an inch in length, that is found in wet places, in woods, and sometimes adhering to the bellus planeris and other fresh-water snails. The lateral bristles are disposed in tufts, and it has no probosces. (Miller, Bonnet, &c.) The body is hairy beneath, and each segment furnished on both sides with four divergent bristles: eyes two, and of a black colour; length, four lines.

BARBATA, in Ornithology, a species of Fringilla that lives in the mountainous parts of Chili. This bird is about the size of a Canary bird; of a pale yellow colour, with green wings, spotted with black and red; and has the chin bearded. It is said to sing delightfully, and to be capable of imitating the notes of other birds with the greatest facility. The bill is white at the base, and black at the tip; head black; chin in the young bird yellow, in a few months this changes black, and appears, when full grown, bearded; this is only in the male bird, for the female has no beard, and is of a cinerous colour, with a few spots of yellow on the wing. Molin. Hist. Nat. Chili. Gmelin. &c.

BARBATA, a species of Musikata, of an olive-brown colour above; beneath greenish-yellow; crown yellow; rump yellow. A native of Cayenne; called by Buffon barbichon de Cayenne; and by Latham the whistled fly-catcher.

The length of this bird is five inches; bill broad, deflexed, and shorter than the whickers. Female greenish-black, yellowish beneath; breast brownish; on the crown an oblong yellow spot.

BARBATED LEAF, in Botany, is a leaf terminated by a bunch of strong hairs.

BARBATELLI, Bernardino, called Pochetti, in Biography, a painter of history, fruit, animals, and flowers, was the disciple of Ridolfo Ghirlandaio at Florence; and from his school he went to Rome, where he applied with such industry, and his mind was so engaged by the objects of his contemplation, that he neglected the necessary refinements of sleep and food. In painting the subjects, to which his attention was principally directed, he not only imitated but equalled nature. His touch was free, light, and delicate, and the colouring of his objects inexpressibly true; and
and holds his merit in his appropriate style of painting; his botanical figures, from laced red picture authors, were much acquired. He was born at Florence in 1542, and died in 1622, at Paukington.

BARBATIA, in Ancient Geography, a town of Asia, towards the Tigris. It belonged to the Arabs, according to Pliny.

BARBATINA, or Berberina, in the Materia Medica, a seed which is efficacious in extinguishing worms from the human body, to which children are chiefly liable; it comes from Peris, and the borders of Mulczow. This seed, when good, is plumy, of an agreeable taste, and very green. Special care must be taken that it be not dyed green, and that the seed of southern wood be not sold instead of it.

BARBATISSUS, in Ancient Geography, a town of Asia, near the western bank of the Euphrates, on the small river Darados, south-west of Nisphorium, about 35° 40' lat.

BARBATO, in Geography, a river of Spain, which runs into the Atlantic, between Cadiz and the rocks of Gibraltar, about 9 leagues south of Cadiz.

BARRATO, or Puerto Barbato, a sea-port town of Spain, in Andalucia, on the coast of the Atlantic, near the mouth of the river Barbata.

BARBATULA, in Ichthyology, a species of Cobitis with fix cinn; head unarmed and compressed. (Linn.) This is the bearded loche of English writers; enchelyopus, &c.

Klein; cobitis flaviolaturn, Ray; fundulus, Marfil.

The bearded loche is a native of Europe and Asia; and is most frequent in fresh-water streams and lakes in mountainous countries. From its habit of lurking at the bottom of the water, on the gravel, it has been called the groundling; but the latter name is now given to the slippery loche, a fish distinguished from the present by having a forked spine under each eye, and its that species of cobitis which Ginelli calls tenia.

This is a fertile creature; it spawns in the month of March and April, and grows to the length of three or four inches, but seldom larger. It feeds on aquatic insects; and, we are told by Mr. Pennant, is frequent in the streams near Amelbury in Wilts, where the sportmen, through frolic, swollow it down alive in a glass of wine.

The loche is found in greater abundance in France, and other parts of Europe, than in England; and these fishes are in such high estimation for their exquisite delicacy and flavour, that they are often transported with considerable trouble from the rivers they naturally inhabit, to waters more contiguous to the estuaries of the great. This is usually performed in winter; and it is necessary to keep the water in continual agitation the whole way, as the fish would otherwise die. Frederic I., king of Sweden, had them brought in this manner from Germany into his country, where they have been since naturalized; a circumstance that leads us to conclude they were either scarce, or not originally native of that country.

In the dorsal fin of the specimen described, are nine rays; in the pectoral eleven; ventral eight; anal seven; and in the tail nineteen.” Donov. Brit. Fishes, vol. i. p. 22.

BARBATUS, in Entomology, a species of Cerambix (Prionus), of a large size, that inhabits South America. The thorax is entire; jaws ferruginous, and very hairy; antenna of a moderate size. (Fabricius.) Antennae rough, extreme joint smooth and compressed; shell pithy; abdomen villous white; legs black.

BARBATUS; a species of Scarabeus; that is unarmed, smooth, and black; vest banded. (Fabricius.) A native of India.

BARBATUS, in Ichthyology, a species of Gobius, with gland-shaped pectoral fins; twelve rays in the first dorsal fin, and thirteen in the second. Its native country is unknown.

BARBATUS, a species of Lophius, of a deformed form, with the lower jaw bearded. (Montic. act. facs. 1779.) Inhabits the seas in the northern parts of Europe, is about three inches and a half in length, and is extremely rapacious. Perhaps not distinct from lophius Vesperidus. Ginelli.

BARBATUS, in Ornithology, a species of Falco, of a whitish red colour, with the back brown; and a black stripe above and beneath the eyes. Ginelli, &c. Vultur barbatius Linna. "ultrixine eagle Albin.

Of this bird there is a variety of a rufous colour, with the back black; head and neck above rufous white; quill and tail feathers brown. Vultur aureus Brill. Vultur buticus Ray. Golden vulture Willughby and Latham. A third variety occurs, falco magnus Ginelli. It, in which the cere is blueish; legs and body beneath chestnut, intermixed with white; tail cinctures.

The first kind inhabits the Alps; the two latter the mountainous parts of Peris. It is larger than the golden eagle, measuring rather more than four feet in length; is very daring, flies in flocks, and will attack men as well as animals.

BARBE, or BARR, in Zoology and Commerce, a kind of horse brought from Barbary, much esteemed for its beauty, vigour, and swiftness. Barbis have a long fine neck, not overcharged with hair, and well divided from the withers; the head is small and beautiful; the ears are handiform and properly placed; the shoulders are light and flat; the withers are thin and well raised; the back is straight and short; the flank and sides are round, and the belly not too large; the haunch bones are properly concealed; the crupper is somewhat long; and the tail placed rather high; the thigh is well formed, and rarely flat; the limbs are fine, handiform, and not hairy; the tendon is prominent, and the foot well made; but the pattern is often long. They are of all colours, but generally greyish. In their movements they are apt to be careless; and require to be checked. They are swift, nervous, light, and make very fine hunters. These horses appear to be the most proper for improving the breed.

The stature, however, is not so large as could be wished. They are seldom above four feet eight inches, and never exceed four feet nine inches, or 14½ hands. It is confirmed by repeated experience, that in France, England, &c. they produce foals which grow larger than their parents. Of the Barbary foals, those of the kingdom of Morocco are said to be the best, and next to these are the Barbis from the mountains. The horses of Mauritania are of an inferior quality, as well as those of Turkey, Peris, and Armenia. (Buffon’s Nat. Hift. vol iii. p. 357.) It is a maxim, that barbs grow ripe, but never grow old, because they retain their vigour to the last, which makes them prized for flations; their mettle, according to the duke of Newcastle, never ceases but with their lives. It is said, they were anciently wild, and ran at large in the deserts of Arabia; and that it was in the time of the cheq Ikhmael, that they first began to tame them. It is also affirmed, that there are bars in Africa that will outrun orriches; such have been ordinarily fold, according to Dapper, for 1000 ducats, or 100 camels. They are fed very sparingly, and, as Dapper says, with camel’s milk. It is added, that in Barbary they preserve the genealogy of their Bars with as much care as the Europeans do that of their noble families; and that in the
the sale of them, they always produce their titles of nobility. The race of horses is much degenerated in Numidia; the Arabs having been discouraged from maintaining it by the Turkish officers, who are fure to become masters of them. The Tingitamans and Egyptians have had the reputation of preferring the best breed both for size and beauty. Some of these are fifteen hands high, and all of them shaped, according to their profile, like the antelope. The good qualities of a Barbary horse, besides the suppoped one of never lying down, and of flitting full when the rider drops his bridle, are to have a long walk, and to flop short if required, in a full career. The Barb is very lazy and negligent in all his motions; he will stumble in walking upon the smoothest ground; his trot is like that of a cow, and his gallop very low and very cay to himself. This sort of horse, however, is for the most part sinewy, nervous, and excellently winded; it is therefore good for a course, if not overweighted. The mountain barbs, which are the largest and strongest, are much esteemed; they belong to the Albarbes, who value themselves much upon them, and are as fond of them as older nations are, so that they are not easily procured. The common barbs have been usually bought in Provence and Languedoc in France, at a moderate price; and many of our persons of fashion in England have them from thence. Barbs, as taught us, fall short of the swiftness attributed to them in their native country; this may be accounted for, partly from the smallness and lightness of their riders, and partly from their not being loaded with heavy saddles and bridles, as in Europe, nor even with shoes. An Arab saddle is only a cloth girt round with a pair of light flippants, and a sort of pommel to fasten them.

Barbard-Barbes, those depending from the English mares, covered by barb stallions, are, by experience, constantly found both better shaped and fitter for the saddle, and stronger for service than their fires. Phil Trans. No. 105.

Barbe, St. in Geography, a town of Mexico, in New Biscay, in the vicinity of which are very rich silver mines; distant 500 miles N. W. from the city of Mexico. N. lat. 26° 10'. W. long. 110° 5'.

Barbes, St. Islands of, lie off the mouth of Green bay, and to the east of Cape Deno, or the south point of White bay in the Marchigian river; on the east coast of Newfoundland, and to the north of Cape Bonavista.

Barbe, or Barbet, in the Military Art. To fire an Barbe, is to fire the cannon over the parapet, instead of through the embrasures; in which case the parapet must not be more than three feet and a half high.

Barbe, or Barde, is also an old term for the armour of the horns of the ancient knights and soldiers, who were accustomed at all points. Della Crufa says, the barde is an armour of iron or leather, wherewith the neck, breast, and shoulders of the horse are covered.

Barbeau, in Geography, a river of Canada, which runs into the Utws. N. lat. 45° 15'. W. long. 76° 20'.

Barbed, in Heraldry. The five petals or leaves which appear on the outside of a full blown rose are called barbed; and are emblazoned thus: a rose gules barbed and seeded proper, the rose is red, the barbed green, and the seeds yellow or grey.

Barbed Arrow, signifies an arrow whose head is pointed of an angular form, and jagged. See Plate of Heraldry.

Barbed Horse is a horse barbed at all points, that is, a war-horse completely armed, furnished, and accoutered.

Barbed and Crufed, a term used in blazoning to express the comb and gills of a cock. The usual term in the English blazon is combed and wattled.

Barbee, or Barben Cross, is by some called cross companion and tournce. See Plate of Heraldry.

Barbel, in Ichthyology. See Cyprinus Barbus.

Barbela, or Verbeia, in Geography, a river of Africa, in Congo, which joins the Zaire near its mouth.

Barbellotize, in Ecclesiastical History, an ancient form of Gnostics, spoke of by Theodoret. The doctrine of the Barbellotize was, that one of the gnos, possession of immortality, had commerce with a virgin spirit named Barbelis, who demanded of him, first presence, then incorruptibility, and lastly eternal life, all which were granted to her: that being one day in a gayer humour than ordinary, she conceived, and afterwards brought forth high, which being perfected by the union of the spirit, was called Christ: the child Christ desired to have understanding, and received it; after which, understanding, reason, incorruptibility, and Christ united together; and from their union arose autogenes, so to. To these fables they add divers others. They were also denominated Barbarian.

Barbella, Emanuel, of Naples. It would be unjust not to belove a few words on this pleasing and peculiar player on the violin of the old school. The father of this singular but worthy and inoffensive character, was an eminent performer on the violin, and leader of the opera band at Naples in the beginning of the last century, during the life of Corelli, when his fellow Geminiani arrived in that city from Rome. (See Corelli, and Geminiani.) On the first hearing of the younger Barbella, he was surprised no one who had heard Giardini and other famous violinists of the new schools. He was not young, indeed, when the parallel was drawn, and solo playing was disregarded at Naples, where vocal composition and singing were chiefly cultivated in the conservatories, and patronized by the public, so that teaching and orchestra playing were Barbella's chief employment and support; and for the latter he was ill qualified by the softness of his tone, and the shortness of his bow. He performed, however, most admirably the famous Neapolitan air, which the common people contantly play at Christmas to the virgin. Barbella executed it with a drone kind of bagpipe bale, in a very humorous though delicate manner. But as a solo player, though his tone was very even and sweet, it was somewhat languid and inferior in force to that of Nardini of the same school, and indeed to that of several others then in Italy; but he knew music well, had much fancy in his compositions, with a tincture of not disagreeable rudecs.

He was most remarkable for his sweet and invonating manner of playing Calabrese, Loccuse, and Neapolitan airs, and among the rest a humorous piece composed by himself, which he calls Tinna Nomia; it is a nursey tune, or Lullaby, excellent in its way, and with his expresion, was extremely captivating.

Barbella was the most obliging and self-satured of mortals; his temper has been said to be as soft and sweet as the tone of his violin.

In a correspondence with the author of this article, who had requelled him an account of the Neapolitan school of music, and above all, of his own studies; as his answer concerning himself was short and characteristic, we shall here insert a translation of it.

"Emanuele Barbella had the violin placed in his hand when he was only six years and a half old, by his father Francesco Barbella. After his father's decease he took lessons of Angelo Zega, till the arrival of Dafquindo Bini, a scholar.
BARBERINO, Francis Da, an Italian poet, was born in 1564 at Barberino, a castle of Valdelsa, and educated for the profession of the civil and canon law at Padua and Elogna. Upon his removal to Florence in 1594, he served two bishops in the way of his profession, and made frequent journeys to the papal court at Avignon. He was honoured with the degree of doctor of laws by Clement V.; and attended the general council at Vienna in 1311. Amidst professional pursuits, he cultivated poetry, and published a work, intitled, "Documenti d'Amore," which treats of moral philosophy, and consists of twelve parts, each of which has for its subject some virtue and its rewards. His style is not disfigured by coarse or elegant, but favours too much of Provencal poetry; and yet the author has been reckoned among the good writers and founders of the language. This poem was first printed at Rome in 1640, adorned with fine figures. Another work, in verse, on the Manners of Women, is prefixed in MS. in the Vatican. Barberino died of the plague in Florence in the year 1348.  

Barberino, in Geography, a town of Italy, in the duchy of Tuscany, seated on a mountain, 16 miles south of Florence. Barberino is also a town of Italy, in the duchy of Tuscany, runneth at the foot of the Apennines, on the side of the river Sieve, four miles west of Scarperia. N. lat. 43° 30'. E. long. 11° 15'.

Barberina, or Blanc, Cape, lies on the coast of Aix, in N. lat. 38° 19', and E. long. 26° 27'.

Barberry, in Botany and the Materia Medica. See Barberis.

Barbereux, in Geography, a town of France, and principal place of a district in the department of the Charente. It has a manufacture of linen cloth, and near it is a medicinal spring. The place contains 1584 and the canton 12,720 inhabitants: the territory includes 235 kilometres and 21 communes. N. lat. 45° 28'. W. long. 0° 15'.

Barbesola, or Barbeusula, in Ancient Geography, a river of Spain, in the country of the Baftulp, Prolemy and Pliny.

Barbesola, Barbeola, or Barbeuf, a town of Spain, in the country of the Baftulp, situated on the rive between Carteia and Transchilda. Prolemy, Pliny, and Mela.

Barbet, in Ornithology, the English name of a genus of birds in Lamth's Synopses, corresponding with that of buco, Linn. See Buco.

Barbeticum Jugum, in Ancient Geography, a principal city of Spain, in Britania.

Barbets, in Geography, the name of the inhabitants of several valleys in Piedmont, particularly those of Lucerna, Andora, Perua, and St. Martin.

Barleyrag, Charles, in Biography, an eminent physician of France during the seventeenth century, was the son of a gentleman of Cerelles in Provence. He studied physic at Aix and Montpellier, and in 1649 took his doctor's degree in the university of the latter place, where he settled; and in 1658, became a candidate for the medical professorship, but on account of his being a protestant, he was ineligible. In the disputations on this occasion he acquired great reputation, and his advice was sought in difficult cases by periphs both in his native country and also in foreign kingdoms. He declined the office of being physician to Madame d'Orleans, preferring liberty to the shackles of a court; and at Montpellier, where he resided, he was attended in his visits by many students to whom he gave clinical instructions. His practice was distinguished by its simplicity,
simplicity and energy; and he introduced many valuable reforms into the state of medicine in that country. He was no less eminent for his condescension and liberality than for his medical reputation, and he alike visited the poor and the rich. The celebrated Mr. Locke was particularly acquainted with him at Montpellier, and testified to his honour, that he never knew two men more similar in their manners and opinions than Barbevrae and his friend Sylvius. After an uninterrupted course of practice for 50 years, he died of a fever in 1669, in his 76th year, leaving a son of his own profession, and two daughters. The only works he published were "Tractatus de Medicina, continens Maladies de la Poitou des Femmes, et autres Maladies selon les nouvelles Opinions," 1670; and "Quoestiones Medicinae medicinae," 1678. A work, intituled, "Medicamentorum Constitutione," &c., published in 1751, is ascribed to him upon uncertain authority, according to the editor M. Farjon. Haller. Bib. Med. Pract. Gen. Histo.

Barbevrae, John, the nephew of the preceding, was born in 1674 at Beziers, whence he withdrew to Lau- fane in 1686. His father designed him for the profession of theology, but his own inclination led him to the study of jurisprudence; and he became eminent in that particular branch of it which comprehended the law of nature and nations. After teaching the Belles Lettres in the French college at Berlin, he was appointed in 1710 to the new pro- fessorship of law and history founded at Lauflane by the magistrates of Berne, which he occupied seven years. In 1717 he was removed to the chair of law at Groningen, and this station he long occupied with general applause. His works are numerous and valuable. His French translation of Puffendorf's "Law of Nature and Nations," and his treatises "On the Duties of a Man and a Citizen," and on "Grotius on the Rights of War and Peace," were en- riched with learned prefaces and notes, which enhanced the value of the originals. He also translated two discourses of Noest, "On the Power of the Sovereign," and "On Liberty of Conscience," a treatise on Bunkeffchin "On the civil and criminal Powers of Ambassadors," some of "Til- lotson's Sermons," and Cumberland's Latin treatise "On Natural Laws." Barbevrae was also the author of several original works. But that which excited the greatest attention was his "Treatise on the Morality of Fathers," 1740. 1728, in reply to the Benedicite Ceiller's "Apology for the Fathers," occasioned by Barbevrae's free strictures on them. His prefac'd work was reduced to the form of a "Treatise on Gaming," in two volumes. 1750. It was printed in 1750; his "Defence of the Rights of the Dutch East India Company against the Pretensions of the People of the Austrian Netherlands," 1752; and "The History of ancient Treaties differed in Greek and Latin authors to the time of Charlemagne," fol. 1759. He also infused literary and critical remarks in different journals, and published some academical discourses. He ended a life of learned labour and moral worth about the year 1747. Nouv. Dict. Histo.

Barbi, in Natural History, a species of Echinorhyn- crus, of an ovate shape, yellow colour, fatulated; neck long, white, cylindrical; and cymathiform (gla s or pot- shaped) at the end, found in the intellina of the barrel. Barbic. See Barbar.

Barbican, in Ornithology, the name of the Gmelinian bucco dubius, or doubtful barbet, in Buffon's Hist, Birds. Barb is also a name given by that writer to all the birds of the bucco genus, which he describes.

Barbican, in Barbican, in our Old W atch-tower; or a tribute towards repairing or building a bulwark.

Barbic. See Barbican.

Barbic, in Ornithology, the name of the Mergus of the gardener's duck, or doubtul barbet, in Buffon's Hist, Birds. Barb is also a name given by that writer to all the birds of the bucco genus, which he describes.

Barbic, in Barbican, in our Old W Vol. 111. 2

Barbic, in Barbican, in our Old W Vol. 111. 2
BAR

two satires, written in verse against Racine, he was unsuccessful. Besides his "factums" for Le Brun, he published some others. Nouv. Dict. Hist.

Barbier, Mary Anne, was a native of Orleans, and ranked among the dramatic writers of France. Her tragedies, and a comedy in prose, were represented at Paris, and printed in one volume, 12mo. The subjects are well chosen, but the characters, and those of the men especially, are without force, and the style is diffuse and prolix. Mad. Barbier was intimate with the abbé Pellegrini, who is said to have inflamed, at least, correction on her works. She died in an advanced age at Paris, about the year 1745. Nouv. Dict. Hist.

Barbier, M. P. first appeared as a new English finger, on the revival of the opera of Almaviva in 1711, while questions were asked in Italian, and answered in English, and a centre. Her timidity on first appearing on the stage, gave birth to an admirable Spectator (No. 134), in which Mr. Addison apologizes for, and commends, diffidence and modesty with a sympathetic zeal and sensibility. It is well known, that this excellent writer, with all his learning and abilities, was never able to perform his part in public as a speaker, when he was secretary of state, and in parliament, long after this paper was written; and here, by a kind of prefiguration, he foretold his fault before it was committed. With regard to Mrs. Barbier's disfear on her first facing an audience on the stage, Mr. Addison has put it in the most amiable light possible: "this sudden defection of oneself," says he, "shews a diffidence, which is not displeasing; it implies at the same time the greatest respect to an audience that can be: it is a sort of mute eloquence, which pleads for their favour much better than words can do; and we find their generosity naturally moved to support those who are in so much perplexity to entertain them. I was extremely pleased," continues he, "with a late influence of this kind at the opera of Almaviva, in the encouragement given to a young finger, whose more than ordinary concern on her first appearance, recommended her no less than her agreeable voice and just performance." This lady was a native of England, who continued to sing at the opera several years, and afterwards was a favourite concert and playhouse finger, till the year 1729.

In the year 1717, it seems as if she had a little vanquished her bashfulness in private; however it may have recommenced her in public; but he had much encouraged sufficient to eloze from her father, who was with a person that was justified to be of a different sex. During her absence, Mr. Hughes wrote the following pleasant verses:

"O yes!—bear all ye beaux and wits,
Muscians, poets, lures, and cits!
All, who in town or country dwell,
Say, can you tale or tidings tell.
Of Tortorella's hafty flight?
Why in new groves she takes delight;
And if in concert, or alone,
The coy and murrkorner makes her moan?

Now learn the marks by which you may
Trace out and stop the lovely airy.
Some wit, more folly, and no care,
Thoughtless her conduct, free her air;
Gay, scornful, sober, indirect,
In whom all contradisions meet,
Civil, affronting, peevish, easy,
Form'd both to charm you and displease you;
Much want of judgment, none of pride,
Modest her drees, her loop full wide;
Brown skin, her eyes of fable hue,
Angel when pleas'd, when vex'd a fiure.

BARBIERI, Giovanni Francesco, called Gualtiero Da Cenzo, an eminent historical painter, was born at Cenzo, a village near Bologna, in 1596; and was at first the disciple of Benedetto Cennini, but afterwards studied for some time in the school of the Caracci. He preferred the style of Caravaggio to that of Guido or Albano, and conceived it impossible to imitate nature truly, without the assistance of strong lights and shades; and on this principle, his light was admitted into his painting room from above. By this opposition of his strong lights and shades he unquestionably gave such force to his pictures, that few, those of Caravaggio excepted, equal them in their effect. His principal attention was employed in acquiring perfection of colouring, from a persuasion that few persons are qualified to discern the elevation of thought which constitutes the excellence of a composition, or are capable of examining even the correctness of any part of a painting; whereas every eye, and even every imperfect judge of a picture, may be feebly affected by the form and beauty of the colouring. His taste of design was natural, easy, and often grand, but without any extraordinary share of elevation, correctness, or elegance. The air of his heads are often dehifcent of dignity, and his local colouring is flat; nevertheless his colours preserve great union and harmony, although his caricatures are not very fresh; and in all his works there is a powerful and expressive imitation of life, which will for ever render them estimable. Towards the decline of life, observing that the clearer and brighter style of Guido and Albano had attracted the admiration of all Europe, he altered his manner even against his judgment. But he apologized for this conduct by declaring that he had formerly painted for fame, and with a view of pleasing the judicious; but now he painted to please the ignorant, and to enrich himself. The most capital performance of Gualtiero is the history of St. Petronilla, which is considered as one of the ornaments of St. Peter at Rome. He died in 1666. Pilkington.

Barbieri, Paul Antonio, Da Cenzo, the father of the preceding artist, was born at Cenzo in 1596, and selected for his subjects fruits, flowers, insects, and animals, which he painted after nature with a lively tint of colours, with great tenderness of pencil, and a strong character of truth and life. Pilkington.

Barbillon, in Ichthyology, a name given by Bourgogne (Act. Parl.) to the Salaria Cirratus of Grelin.

Barbing is sometimes used in Ancient Statutes for shearing. Cloth is not to be exported till it be barbed, rowed, and thorn. 3 Hen. VII. c. 11. BAR.
BAR

BARBISTROSTRIS, in Entomology, a species of Curculio, found in China and some other parts of Asia. It is black; stout bearded; anterior legs tridentated. Fabricius. Describ. Insect. China, &c.

BARBITANI MONTE, in Ancient Geography, mountains of India, on this side the Ganges, in which according to Ammianus Marcellinus, are the springs of many rivers that flow into the Indus.

BARBITON, an ancient musical instrument, of which nothing is known but the name; and Rouffaen has not even ventured to give us that. Complaints are frequently made of the darkness in which critics, commentators, and historians have the subject of ancient music; which none have more cause to lament than those who have spent the most time and labour in its investigation. But as no record or memorial has been found, which ascertain the invention, form, or species of instrument called the barbiton, would mere conjecture satisfy the complaints? Melis. Grammar. Franscy and Cattillou, more courageous than the citizen of Genoa, have told us, in the new Encyclopaedia, all that is pretended to be known about it; though the former begins by telling us that it is an instrument about which nothing is known. The ancients and moderns have frequently confounded it with the lyre. Dacier conjectured that it was a flaring instrument; and deriving its name from barbitum, which implies thick fringes of flaxen thread, he concludes that it was an instrument with thick fringes. It is certain that flax was in use for flaring to musical instruments, before the art was known of making them the bards of animals. Horace calls this instrument Lesbian, Lybicum barbiton, ode i. lib. 1.; and 12 of the same book, Ilyto primo musylato, "Thou, O barbiton, first touched by a citizen of Lesbos," meaning Alcæus, to whom he ascribes the invention. But, says M. Castellon, we may conclude from what Musfionis affirms of this instrument, in his treatise "De Luxu Greorum," that they made a kind of concert with the pæa of the Lydians. (See Pæctis.) He affirms us that Tersander was the inventor of it. Julius Ptolœus also calls it barbiton, barbiton. Athenæus relates that they likewise called it barœus, and attributes the invention to Amacenon. We hope the grumblers will be perfectly enlightened by this clear, confident, and satisfactory account.

BARBOL, or BARBOL, in Ichthology. See BARBUS.

Barbuls, in the Mangle, knots of superfine flesh growing in the channels of a horse's mouth; that is, in the intervals which separate the bars; and obstruct his eating. There are also called barbus; and obtain in black cattle as well as horses.

For the cure, they cast the beef, take out his tongue, and clip off the barbels with a pair of scissors, or cut them with a sharp knife; others choose to burn them off with a hot iron.

BARBONI, in Ichthyology, a name formerly given by many to the Mullus Barbatus; which see.

BARBONNE, in Geography, a town of France, in the department of the Marne, and chief place of a canton in the district of Sezanne, 14 leagues south from Sezanne.

BARBORA, an island of Africa, opposite to the kingdom of Adel, so called after a town of the same name upon the neighbouring continent. This island, which is almost contiguous to the Terra firma, is very fertile, and produces plenty of corn, fruits, and cattle. The inhabitants are negroes clothed in the fashion of the natives of Adel, industrious in trade, and great breeders of cattle, for which the soil affords excellent pasturage. The produce of this island is exported into other countries. The city of Barbora lies at the bottom of a convenient bay; and was for a long time a kind of rival in commerce with Zella, and so held the place of resort for foreign merchants. It is situated over against the city of Aden, and made once a considerable figure, but was plundered and burnt by the Portuguese fleet in the year 1518; but the inhabitants, being previously apprized of their designs, conveyed themselves and their valuable effects away.

BARBOSA, ARIAS, or Ayres, in Biographical, a native of Aveiro in Portugal, and one of the refusers of classical literature in his own country and in Spain. Having commenced his education at Salamanca under many disadvantages, he pursued his studies, particularly that of Greek, which he cultivated with great ardour, at Florence, under Angelo Politianus. After his return to Salamanca in 1493, he taught there for 20 years, in connection with Antonio de Lebres, who, with Andrew de Refenda, was also one of the principal promoters of useful learning in Spain. Barbosa directed special attention to poetry, and published a small volume of Latin poems, which were commenced for the harmonious structure of the verse. He was afterwards employed for seven years as preceptor to the two princes of Portugal, Alphonso and Henry; and then retired to domestic life, in which he died at an advanced age in 1542. Besides the poems above mentioned, Barbosa published several works, which contributed at the time to the progress of literature, but are now forgotten; such as, "Commentaries on the poem of Auctor," "Quodlibetica Quæstiones," "De Prolodice," &c. Moret. Nouv. Dict. Hist.

BARBOSA, Peter, a celebrated lawyer, was born at Viana, in Portugal, and became first professor in the university of Coimbra. Although he occupied several important stations, and was appointed by Philip II. of Spain, when he became master of Portugal, one of the four counsellors of the council of state, and afterwards chancellor of the kingdom, he prosecuted his professional studies; and, in 1507, he published an ample commentary on the article in the "Digelts," on the recovery of dower after the dissolution of marriage. In 1613, the works left by him in MS., which were commentaries on the "Digelts," art. "On Judgments," were published by his nephew, and so well received, as to be reprinted at Frankfort in 1715. Other pothumous treatises were published at Lyons in 1652. Moreri. Nouv. Dict. Hist.

BARBOSA, Emanuel an eminent Portuguese lawyer, was born at Guimaraes, and was king's counsellor for the province of Alentejo. In 1618, he published a treatise relative to contracts, last wills, and others, according to the Spanish and Portuguese law. In 1638, he published a work, "De Poteatate Episcopi," and in that year he died, aged near ninety years. Moreri. Nouv. Dict. Hist.

BARBOSA, Augustin, son of the preceding, studied civil and canon law under his father, and afterwards at Rome, with incessant industry, searching libraries in the day, and composing in the night. It is related of him, that he received a sum of manuscript wrapping of some fifty livres, which he purchased, and that he refused the remainder from a similar use; and thus formed the work "De Officio Episcopi," which he corrected and published in his own name. A prejudice was thus conceived against him, and several of his treatises on the canon law were abridged to his father. He was, however, a very judicious man; and on his return to Spain in 1632, he pursued the same kind of life which he had passed at Rome. His skill in ecclesiastical causes occasioned his promotion, in 1634, to the bishopric of Ugras.
to, in the territory of Otamato. Having been consecrated at Rome in the following year, he returned to Ugento with a view of performing the duties of his office, but died there within a few months. His works were numerous, and were printed at Lyons in 1716 and the following year, in 16 tomes folio. Moreiri. Nov. Ditt. hilf.

BARBOSTHENES, in Ancient Geography, a mountain of Greece in the Peloponnesus, 10 miles from Lacedaemon. Livy.

BARBOT, Penn.; BARBOY; Roland; in Ichthyology, synonymous names of the species of Gadus called Lota by Linnaeus.

BARBOTES Rocks, in Geography, are two rocks which are about half a league N.N.W. from the Cambrmers, and appear every tide.

BARBOTINE, a seed otherwise called semen fontanenum, and semen contra vermes, in English wormseed.

BARBOULT Point, lies within the south-west point of the bay of Cancale, to the east of St. Malo, on the coast of France.

BARBOUR, or BARBER, John, in Biography, an eminent divine, historian, and poet, was born in the city of Aberdeen, as some say, about the year 1350, but according to others, in 1326. Having received a learned education, he entered into holy orders, and was promoted by King David II. to the archdeaconry of Aberdeen, A.D. 1356. Such was his love of learning, that he continued to prosecute his studies after his promotion; and with this view he prevailed on his own sovereign, David Bruce, with whom he was in great favour, to obtain permission from Edward III. to study at Oxford. The grant for this purpose was dated at Westminster, Aug. 13th, A.D. 1357. He was also appointed by the bishop of Aberdeen, one of the commissioners for the ransom of David II. king of Scotland; and he obtained permission from Edward III. A.D. 1365, to travel through England to St. Denis, near Paris, with six horsemen as his attendants. Barbour was not only famous for his extensive knowledge in the philosophy and divinity of those times, but still more admired on account of his admirable genius for English poetry; in which he compos'd, as he tells us, in 1375, a history of the life and glorious actions of Robert Bruce king of Scotland, at the demise of King David Bruce, his son, who granted him a considerable pension for his encouragement, which he generously bestowed on an hospital at Aberdeen. This work is not only remarkable for a copious circumstantial detail of the exploits of that illustrious prince, and his brave companions in arms, Randolph earl of Moray, and the lord James Douglas, but also for the beauty of its style, which is not inferior to that of his contemporary Chaucer. This poem passed through about twenty editions in Scotland since the year 1616, in which the first edition, that can be deciphered, was printed at Edinburgh, in 12mo. But these editions were all modernized. An edition of this most ancient production of the Scottifh muse extant, in the language and orthography of its author, from a MS. written in 1489, and preferred in the advocates library at Edinburgh, was printed by Mr. Pinkerton, under the title of "The Bruce," with notes and a glossary, in 1750, in 3 vols. 12mo. The following versis, distinguished by their softness, afford a specimen of the author's talent at natural description, and also of the state of the English language in his time.

"This was in midst of month of May, When birds fig on lila spray, Meland their notes, with feemly foun, For softness of the sweet seafoam."

And leaves of the branchis breedes, And blofomis bright, bedefe them, breeds, And fields flowren are with flowfers Well favouring of feir colours; And all things worthis, hybhs, and gray." Barbour is laid to have died at an advanced age in 1356, but the time and circumstances of his death are not satisfactorily ascertained. Henry's History, vol. viii. p. 249. Pinkerton, ubi supra. Wharton's Hist. Eng. Poetry vol. 1. P. 318.

BARBUDA, or Barbuda, in Geography, one of the British Caribbean islands in the West Indies, a small island, about 20 miles long and 12 broad, and lies about 15 miles north-east of Montserrat. This island was planted soon after the English had settled upon St. Christopher's, in 1628, and called "Dulcinea" from its beautiful appearance. It is the property of the Codrington family, whose ancestor Colonel Codrington obtained a grant of it for his important services to the crown of England in the West Indies, and is said to yield above 5000l. a year. Upon his death in 1710, he bequeathed two plantations in Barbadoes, and part of Barbuda, valued at 2000l. per annum, to the society for propagating the gospel for the instruction of the negroes in Barbadoes and the other Caribbean islands in the Christian religion, and for erecting and endowing a college in Barbadoes. This is the only proprietary government of all the English Caribbean isles, and the appointment of a governor is in the Codrington family. The land lies low, but is fertile; and the inhabitants are chiefly employed in breeding black cattle, sheep, kids, fowls, and all kinds of domestic flocks; in planting Indian corn, and in other parts of husbandry; and they supply the adjacent farming islands with these articles. The island, however, is capable of yielding, by cultivation, citron, pomegranates, oranges, raihins, Indian figs, maize, cocoa-nuts, cinnamon, and pine-apples, with various kinds of wood and drugs, such as brasil, ebony, pepper, and indigo. There are some large serpents upon this island, which, not being poisonous, are useful in destroying rats, toads, and frogs; and others so venomous, that their bite proves mortal, unless an antidote be applied in the space of two hours. The coast abounds with rocks; but on the west side of the island there is a well-feltered road, and there are two shoals, which run more than two leagues into the sea, from the north-west and south-west points. The inhabitants are computed to be about 1500. N. lat. 17° 45'. W. long. 61° 50'.

BARBUE, Riviere-a-la, a river of North America, empties itself into lake Machigan, from E.S.E. between Rainif and Marame rivers. Its mouth is 60 yards wide, and lies 72 miles N. by W. from fort St. Joseph. This is also the name of a river, which discharges itself into lake Erie, from the N. by E. 40 miles W.N.W. from the extremity of Long point, in that lake, and 22 E. by S. from Tonty river.

BARBULÆ, in Botany, a name given by Pliny to the semi-tocali.

BARDUS, in Ichthyology, a species of Cyprinus, having seven rays in the anal fin; heards four; second ray of the first dorsal fin serrated on both sides. Linn. Mufl. Ad. Fr. 8c.

This is the barbel of the English; a common inhabitant of most fresh waters in Europe, and easily distinguished from the other species of carp, or cyprinus genus, to which it belongs, by the upper jaw being advanced far beyond the lower one, and in having the four heards appendant, from which the appropriate name of barbus or heard is derived. This fish, during
during the summer, prefers the rapid currents and shallows of rivers, and retires at the approach of winter to the more full and deeper places. They live in societies; lurking in holes along the sides of the water under shelter of the steep banks, and feed on smaller fish and worms and flesh of all kinds, for which they dig in the banks like swine. In the daytime they love to lurk occasionally among weeds, and between the stones in retired parts of the river, and wander out at night in search of prey. They spawn in April, and begin to be in great numbers in May and June.

The flesh of the barbel was never in great esteem for the table. Mr. Pennant quotes a passage in Autolycus, which, as he observes, is no panegyric on its excellence, for he lets us know it loves deep waters, and that when it grows old, it is not absolutely had:

"Laxos exercitae barbae natus
Tu melior pejor evo, tibi contiguit uni
Spirantium ex numero non inaudita fameus."

And he adds himself, that "they are the worst and coarsest of fresh-water fish, and seldom eat but by the poorer sort of people, who sometimes boil them with a bit of bacon to give them a relish."

"The barbel," says old Walton, "though he be of a fine shape, and looks big, yet he is not accounted the best fish to eat, neither for his wholesomeness nor his taste, but the male is reputed much better than the female, whose spawn is very hurtful."

Again, when speaking of Rondeletius, he makes this remark on the spawn, "we agree with him, that the spawn of the barbel, if it be not poison, as he says, yet that it is dangerous meat, especially in the month of May; which is so certain, that Gesner and Gaffius declare, it had an ill effect upon them even to the endangering of their lives."

Sir John Hawkins, in his Annotations, inclines to the same opinion, and gives an instance of his servant being taken dangerously ill after having incautiously eaten of this fish. M. Bloch, and some other ichthyologists, contend that this is a vulgar and most absurd prejudice. M. Bloch in particular observes, that himself and all his family have eaten the spawn of the barbel, and never experienced the slightest ill effects from it. Donov. Brit. Fishes.

The time for taking this fish is very early in the morning, or late in the evening: the place should be baited with chopped worms some time before; and no bait is so good for the hook as the spawn of the salmon, or some other fish: in defect of these, lob-worms will do; they must be very clean and nice, and the hook carefully covered, otherwise he will not touch them. Old cheese steeped in honey is also a very fine bait. The best season for angling for this fish is from May to August.

BAREY, in Geography, a small bailiwick of Germany, in the circle of Upper Saxony, forms a part of the circle of Wittenberg, and was granted in 1748 and 1765, to the count of Reuss, and the society of united brethren, or Moravians.

BARBY, is also the name of a town of Germany, in the circle of Upper Saxony, situated on the Elbe, near the mouth of the Saale, in which is a Moravian academy for the instruction of youth, 14 miles N.W. of Dessau, and 14 S.S.E. of Magdeburg. Lat. 51° 37'. E. long. 11° 51'.

BARBYLA, in Botany, a name by which Theocritus, and others of the early writers, have called the common damask prune.

BARCA, in Geography, an extensive desert country, situated on the south coast of the Mediterranean, between Tripoli and Egypt, and forming part of the great desert, or Sahara.

It extends in length from west to east from about the 30th degree of longitude to the 30th degree, and in breadth from north to south about 50 leagues, though its confines on the south side are very imperfectly ascertained. It is, in general, a dry and barren land, whence the Arabs have called it "Sahara," or "Ceyuran Barka," that is the "Defert," or "Road of Whirlwinds and Hurricanes." Water is scarce; and, except in the neighbourhood of its towns and villages, if they may be so called, where the ground produces some grain, such as corn, millet, and maize, it is quite sterile and uncultivated. The articles which the poor inhabitants produce they are obliged to exchange with their no less indigent neighbours for dates, flour, and camels. This country forms part of the ancient Cyrenaica and Marcomaria (see Cyrrenatica and Marcomaria); in the most desert and dangerous districts of it stood the temple of Jupiter Ammon. (See Ammon.) This spot, though in some respects pleasantly situated, is surrounded by quick and burning sands, which are very pernicious to travellers, and sometimes overwhelm whole caravans. Against this temple Cambyses, and an army of 50,000 men, marched from Thebes in Upper Egypt; but their fate is uncertain, as they never returned either to Egypt or to their own country. (See Ammon.) This country is indeed so desert, that there is no travelling through it without the aid of a compass, or the direction of the stars; and though it was once the thoroughfare for caravans from Barbary and Morocco to Mecca, yet it has been infested with wild Arabs to such a degree, that they are obliged to fleer 50 leagues about to avoid being plundered. The French geographers divide the country of Barca into two parts; one called the kingdom, and the other the desert, the former hath, according to their statement, some considerable ports, towns, and villages, and is under the protection of the Porter, governed by a calh, who is the bailiff of Cairo, and resides at Tripoli; but for this they have no sufficient authority. According to Sanfón and Baudrand, the other part, which extends along the eastern coast, called by them the eastern shore of Tripoli, reaches from the port of Solomon or Solyman, to the Gulf of Sydna; but this coast is commonly distinguished by the name of Derna, one of the most considerable of its towns and ports; besides which it has several others, and the ruins of many more, which are now reduced to poor villages. The most remarkable is the cape Raccellino, styled by Ptolemy Cherifoneus, because it forms a peninsula; and the furtherthest towards Egypt is the town of Angola or Onguida. (See Anguis. Between these two, are many others differently placed and named, as the Porto Tabara, formerly Barathas, Baratra, and Patriarcha, cape de Lince or Loco, anciently Promontorium Caraliunum, Brazil Molufam, the haven of Salina or Salona, supposed by some to be the ancient Portus Panormus, and Galium, and by others the Portus Catabamhus, which our latest geographers place on the most easterly verge of the Barcan coast, next to the confines of Egypt. To which may be added the large valley of Carto Sapiucus, the ancient Catabamhus, extending quite to Egypt, opposite to the spot where the temple of Jupiter Ammon stood. From these we proceed to Porto Albertene, or the Sultan's port; that of Cagusi, formerly Trifachi; the cape and haven of Ruxa, anciently Pareonium; and, lastly, the city of Barca, which gives name to the whole province, and lies farther inland, on the eastern coast of the Gulf of Sydra. This was the capital of the Barci, and is mentioned by Strabo, Pliny, Sclavus, and Ptolemy; and is said by the two former to have occupied the spot on which Ptolemais was afterwards built; but the two latter are of a different opinion.
BAR

tion. It seems to have flood to the west of Cyrene, and
had a port near the Greater Sytys. As it was a maritime
city, it is most probable that it flood by the part of the
Barcet, and not where Barce flood; more especially as that
capital was 100 stadia from the sea, according to Scylax.
Herodotus says, that Barca was built by the brothers of Ar-
coffrae H. king of Cyrene, more than a generation before
the beginning of the reign of Caresus; but it is more probable,
that it was of Phenician, if not of Egyptian or Libyan ex-
traction; for Barca was a Phenician name, well known in
those parts of Africa, as we learn from Sinus Italicus, and
others. Servius intimates, that its citizens came originally
from Carthage, which would lead us to conclude, that
Barca, Dido's brother, who attended her into Africa, with
some of his countrymen, settled here. It sufficiently ap-
pears from Vigil and Sinus, that the Barcet spread them-
Lies over several considerable parts of Libya, and, accord-
ing to Servius, their metropolis made the greatest figure of
any city in this region, except Cyrene. St. Jerom confirms
these last authorities, when he affirms that this town was
situated in a desert; and that its inheritants, or at least their
descendants, differed themselves over several districts, lying
as far to the westward as Mauritian, and the eastward as
India. The Barcet learned (says Stephanus) the art of
managing horses from Neptune, and of driving chariots from
Minerva. The modern kingdom and desert of Barca un-
dxoubtedly derived their name from the Barcet; and we
may hence infer, that these people formerly held a consider-
able rank among the various nations of Libya.

What is the present condition of the towns of Barca, what
is their commerce, and how they are governed, we have no
authentic documents for ascertaining. The maritime towns
are, probably, under the protection of the Porte; but it is
not certain whether they are under the government of the
basilic of Egypt or Tripoli, or they have formed themselves
into free states like those of Algiers and Tunis. This how-
ever is certain, that the inhabitants of the maritime towns
are more civilized than those within land. The first profes-
Mahometanism, and have imbibed some notions of humanity
and justice; but the latter, and especially those of the desert,
who have neither religion nor any appearance of worship
among them, are altogether brutish and savage, and live
wholly upon theft and plunder, like all other wild Arabs.
By them this tract, which was before a barren desert, was
first inhabited. Deficient and indigent in the extreme, they
are said also to be the ugliest of all the Arabs; their bodies
being meagre, their faces grim, and aspect fierce and ra-
venous; their garb, which is commonly tripped from the
pailengers and pilgrims, tattered with long wearing; while
the poorest of them want rags to cover their nakedness.
They are likewise reported to be resolute and expert rob-
bers and plunderers; but deriving a wealthy supply from
their own neighbourhood, they are compelled by necessity to
extend their excursions as far as Numidina, Libya, and other
sothern parts, where they commit many atrocious acts of
cruelty. So indigent and famishing are these Barcetans, that
they commonly part, pledge, and even sell their children, for
procuring the necessities of life, to the Sicilians, and other
neighbouring Christians, from whom they have most of their
corn, especially before they set out on any long expedition.
The chief towns of Barca are Derna, the capital and resi-
sence of the fagge, Tolometa or Tolomata, and Grena
vol. xv. p. 196, &c.

BARCAROLO, a Spanish word, which the French pro-
nounce Bacaceo or Bacallou. By this last name the Barques
most commonly call the fish which we style eel; and those
people call also the island which we call Newfoundland, the
isle of Bacallou (Cod Island), because of the great plenty
of cod caught there. There is, however, a league to the
west of that large island, another small one, which is more
particularly called Bacalluo.

BARCALON, an appellation given to the chief mini-
ster of the emperor of Siam, to whom belongs the care of
trade both within the kingdom and out of it, the superin-
tendence of the royal magazines, the receipt of the revenues,
and the management of foreign affairs.

BARCA-LOXEA, a large Spanish fishing-boat, navigated
with lug-falls, and having two or three masts. There are
very common in the Mediterranean. See Barc.

BARCA, in Ancient Geography, a people of Asia, in
the vicinity of Hyrcania. They are placed by M. D'Ar-
ville, on the coast of the Caphian sea, near one of the mouths
of the Oxus.

BARCAROLLA, in Music, a kind of song in the Ven-
etian language, sung at Venice by their gondoliers or water-
men, in their boats or barges. These airs (fays Rouffeau)
are composed for the common people, and often by the gond-
oliers themselves. They have so much melody, and such
an agreeable accent, that there is not a musician in all Italy
who does not pique himself on knowing some of them. The
being admitted gratis into a gallery appropriated to them in
all the theatres, enables gondoliers to form their cars and tale,
without trouble or expense, so that they compose and sing
their airs, without altering their natural simplicity, in the
fyle and expression of persons not ignorant of the refrains
of music. The words of these songs are commonly
jocose, and more than natural, like the conversation of those
bards, but such as the faithful picture of the manners
of a people can please, and such as are likewise partial to
the Venetian dialect, soon become passionately fond both of
the words and music of these airs, chiefly known in England
by the title of Venetian ballads, of which travellers into Italy
make collections.

The late earl of Leicester, one of the subscribers to the
royal academy of musick in 1720, used to say, that at the first
establishment of operas in England, the nobility and gentry,
in imitation of the Venetians, suffered their servants to have
admission, gratis, into the upper gallery, with a view to
improve the national taste in singing; but instead of profiting
or deriving pleasure from this privilege, they became so noisy
and insolent, that about 40 years ago, like our first parents,
they were driven out of paradise.

We must not forget (fays Rouffeau) to remark, for the
style of Tasso, that most of the gondoliers know the chief
part of his poem "Gierusalemme Liberata," by heart, and
form the whole; that they pass their former nights in their go-
ondolas, singing it alternately from bank to bank; that the
name of Tasso is an admirable barcarolla; that Homer only had
the honour of being thus sung before him; and that, since
his time, no other Epic poem has been thus distinguished.

BARCAROTA, in Geography, a town of Spain, in
Estramadura, 4 miles from Almendreloro.

BARCE, in Ancient Geography. See Barca.

BARCE, a town of India, built by Alexander, on the sea-
coast, in memory of his exploits, and where, according to
Justin, he erected altars.

BARCELONA, in Geography, a rich and strong city
and sea-port of Spain, in the province of Catalonia, of which
it is the capital, and the see of a bishop, suffragan of the arch-
bishop
B R A C A R 

Bishop of Taragona. It was originally founded by Hamilcar Barcas, the father of Hannibal, and from him called "Barcino," about 250 years before Christ. It was reduced by the Romans, and continued subject to them till the kingdom of Spain was overrun by the Goths and Vandals, and afterwards by the Saracens and Moors. At the beginning of the sixth century it was poached by the Moors, under the government of Zade. This governor having abused the clemency of Charlemagne, and by his peridious behaviour provoked his son, Lewis king of Aquitaine, Barcelona was invaded, and the generals who were intrusted with the command of the siege had orders not to abandon it till Zade was delivered into the hands of Lewis. The Moor made an obstinate resistance; but finding that it was impossible to preserve the city any longer, after a defence of many months, he determined to throw himself upon the emperor's mercy, and was condemned to perpetual exile. At length, however, the city surrendered, and the king of Aquitaine, appointed one Berà, count of Barcelona. The city continued subject to him and his successors, who were distinguished by the title of "Counts of Barcelona," from the year 892 to 1121; when it was united to the crown of Aragon by the marriage of Don Raymond V. count of Barcelona, with Donna Petronilla the daughter of Don Ramiro the monk, and heirress of Aragon. In consequence of the revolt of the Catalans, in 1455, Barcelona was besieged by Don Juan II. king of Aragon, in 1471. The siege was prosecuted for a considerable time with vigour, but without effect; however, in 1472, it capitulated on its own terms; and the king, upon his public entry into the city, confirmed all its privileges. In 1640, the Catalans, having shaken off the yoke of the Spaniards, called in the French to their succours; and they continued masters of the capital till 1652, when, after a siege of fifteen months, it surrendered to Don Juan of Austria. In 1657, it was again taken by the French under the command of the duke of Vendome, but restored to the same year to the Spaniards by the peace of Ryswick. Although the inhabitants of Barcelona had taken the oath of fidelity to the king of Spain, Philip V. and received from him a confirmation of their privileges, they invited the English and Dutch, and the governor was obliged to surrender the town to the allies in 1705, when Charles, afterwards emperor, was received and proclaimed king. In the following year, Philip, affrighted by the French, affailed the city, and took the fortresses of Montjuich; but the fleet of the allies advancing to the relief of the besieged, he was compelled to abandon the enterprise and to retire from the place, May 12th 1706. By the treaty of Utrecht, in 1713, the troops of the emperor evacuated Catalonia; but the inhabitants of Barcelona perished in their revolt, and would not acknowledge Philip for their king. Accordingly they suffered blockade for a year, which was followed by a terrible bombardment; and at length, after a siege of sixty-two days, from the opening of the breach by the duke of Berwick, the town was taken by the 14th of September. By the moderation of the conquerors, the city was saved from pillage, but the inhabitants were deprived of their privileges; they have since, however, been re-established, and in 1715 a citadel was erected to keep them in awe.

Barcelona is now one of the largest and handomest cities in Spain, and is reckoned the third most considerable city in the kingdom. It is situated on a plain by the sea-side, open to the south-east, but protected by hills on the north and west, so that it affords a healthy and delightful residence; however it is subject to a fog brought on by the east wind. The city is surrounded by a good brick wall, round which is another, with fourteen bastions, horn-works, ramparts, and ditches. The ramparts are high and impacous, and a great number of carriages may be seen every evening driving upon them for pleasure. The city is divided into two parts; the old and the new, which are separated from each other by a wall and a large ditch. The streets are narrow and crooked, and the churches rather rich than beautiful. Barcelona contains several considerable edifices; that called the Torre, or the arsenal, is of large extent; and a prodigious gallery, containing twenty-eight forges, has been erected in it within a few years. The other most remarkable buildings are the cathedral adorned with two high towers, the church of Notre-Dame, the palace of the bishop, the exchange, the palace of the governor, that where the nobility of the country assemble, called "La Càfà de la Deputacion," and that of the inquisition. The hospitals contain about 1400 indigent poor; and in the house of correction are sometimes found women of rank, who have been guilty of drunkenness, or other low vices. The harbour is spacious, deep, and secure, and defended on one side from the winds by a mountain called Montjuich, which rises in the middle of the plain near the city, runs into the sea in the form of a promontory, is covered with vineyards, gardens, and groves of trees, and a strong fort for defending the city, and furnishes a quarry of fine hard freestone; and on the other side by a large mole; having a light-house with a small fort and garrison at the extremity. Into this harbour 1000 vessels are supposed to enter during peace, and of these 500 are Spaniards, 120 French, 100 English, and 50 Danes. Barcelona is a place of great trade, on account of the convenience of its harbour; although none but small vessels can enter within the mole. Its chief manufactories are silk, cotton, wool, and excellent fine-arms and cutlery: its chief imports are corn, fish, and woollen goods, and its exports, wine, brandy, cloth, and leather. Silks from Lyons, rockings from Nîmes, several kinds of stuff and cottons although manufactured in the country, and particularly dried cod, an article for which Spain is said to pay annually to the English three millions of pistoles, pass into Catalonia through this port. About twenty years ago, a very large cannon foundry was established in this city, under the direction of M. Maritz, a Switz; and it has several glass-houses. The inhabitants are industrious and active, and their number is said to exceed 100,000; they are hospitable to strangers; the women are as handsome as any in Spain, lively in their conversation, and less restrained in their conduct than in other parts of the country. Barcelona was erected into a county by Charlemagne, and became an independent sovereignty in the year 875 or 884. The king of Spain is called the count of Barcelona. The diocese contains 213 parishes, besides 8 in the city. It is distant 13 leagues E.N.E. from Taragona, and 92 E.N.E. from Madrid. N. lat. 41° 26'. E. long. 2° 13'.

BARCELONE, a town of France, and principal place of a district in the department of the Lower Alps. It anciently belonged to Piedmont, and was ceded to France by the treaty of Utrecht in 1713. It is situated on the right bank of the Ubaye, in a valley of excellent pasturage, four leagues S. of Embrun, and 81 N.N.E. of Digne. The place contains 2182 and the canton 8160 inhabitants; the territory includes 290 kilometres and nine communes. N. lat. 44° 25'. E. long. 6° 45'.

Barcelona De Vitrolles, a town of France, in the department of the Lower Alps, and chief place of a canton in the district of Sifforre; the place contains 617 and the canton 1017 inhabitants; the territory includes 621 kilometres and two communes.

Barcelonnes, a town of France, in the department of
of the Gea, and chief place of a canton in the district of Nogaro, seated on the Adour, containing about 12000 inhabitants; three leagues S.W. of Nogaro, and 91 W.N.W. of Mirande.

BARLOTE, a sea-port town of the East Indies, on the coast of Malabar, between Goa and Mangalore, in a district ceded to the British by the treaty of 1799. It has a good harbour, and the Dutch had formerly a factory in this place, which carried on a considerable trade in pepper. N. lat. 13° 35', E. long. 74° 45'.

BARCELLOS, a town of Portugal, with the title of a duchy, in the province of Entre Douro e Minho, not far from the sea, on the river Cavado, eight miles W. of Braga. N. lat. 41° 20', W. long. 7° 5'.

BARCHESSO, or Barches, were formerly a kind of ship gun; not unlike fowlers, only shorter, thicker in metal, and wider based.

BARCHIN, in Geography, a town of Peria, in the province of Kerman, 120 miles S.E. of Sirjan.

BARCHOHEBAS, or Caza, in Biography, a false Messiah of the Jews, who took advantage of the animosity excited among his countrymen by the professions of the emperor Adrian, when he founded his new city of Mediala on the ruins of Jerusalem, about the year 134, assumed the name of Barchohebas, or child of the Star, in allusion to a prophecy of Balaam (Num. xxiv. 17), and pretended to be the long-expected deliverer of his nation. He chose for his predecessor the famous Akiba; and collecting together an army of 200,000 men, he formed himself the Messiah and prince of the Jewish nation. However he deferred declaring war against the Romans, till Adrian had quitted Egypt, so that it did not break out till the 17th year of that emperor's reign. Adrian seems at first to have neglected this new revolt; but when he perceived that it was likely to become formidable, he sent Titinius Rufus with a strong reinforcement to quell it. This force being insufficient to restrain the depredations of these banditti, who massacred all the Romans and Christians that fell in their way, Julius Severus was recalled from Britain, and sent at the head of an army against the impostor. This general laid siege to Bither, which was resolutely defended, till Barchohebas was slain. The town was then carried by storm, and this event, which, according to Eusebius, happened in the 18th year of Adrian, was followed by a most dreadful slaughter of the Jews. Crevier's Rom. Emp. vol. vii. p. 188, &c. Bafnage, Hist. des Juifs, t. vii. c. 12. Mod. Uni. Hist. vol. x. p. 437, &c. See Asia.

BARCAUL, in Geography, a town of Spain, in the province of Granada, five leagues from Guadix.

BARCHUSEN, or Barchhausen, John Conrad, in Biography, a learned physician and chemist, was born at Horne in the county of Lippe, 1666. After a liberal education, and a course of travelling through the principal cities of Germany with a view to his improvement in pharmacy and chemistry, he became physician to the Venetian general in his expedition to the Morea in 1694; and on his return settled at Utrecht, where he obtained permission to teach chemistry, in which employment he continued till the time of his death in 1717. His character was distinguished by integrity and zeal for public good, as well as by indefatigable industry in the pursuit of knowledge; without offending any very extraordinary share of genius or solidity of judgment. His works are "Synopsis Pharmaceutica," Frankf. 1690, and Utrecht, 1696, 8vo.; "Pyrophoria," Leyd. 1698, 4to, enlarged and published at Leyden in 1771, under the title of "Elementa Chemia" &c. "Acronomata ad Jactrochymiam et Phyficam Spectantium," Utr. 1703, 8vo.; "Triforia Medicinae," Amfil. 1712, 8vo.; published with enlargements under the title of "De Medicina et progressa Difertationes," Utr. 1725, 4to, in which work an account is given of all the facts and theories of medicine from the earliest times to the author's own age, but with less accuracy, especially in relation to the ancient writers, than those of Le Clerc and Freind; "Synopsis Pharmaceutica," Leyd. 1712, 4to; "Compendium Rationum Chemicae," Leyd. 1713, 4to; "Collecta Medicina Practica Generalia, et Dialogus de optima Medicum rum ficta," Amfil. 1713, the Halley Lib. Med. Pratet.

BARCINO, in Ancient Geography, a town of Hispании Tarraconensis, and capital of the Latetani; now Barce- lona.

BARCLAY, Barley, of Barklay, Alexander, in Biography, an elegant British writer of the 16th century, was a native either of England or Scotland, but probably of the latter country. About the year 1495, he came to Oriel college, Oxford, and having distinguished himself by his parts and learning, he travelled on the continent and acquired a competent knowledge of the languages spoken in Holland, Germany, Italy, and France. On his return to England, he became one of the priests of St. Mary Ottery in Devonshire, and afterwards a monk of the monastery of Ely. After the dissolution of this monastery in 1539, he was presented successively to several livings, the last of which were those of Baddow Magna in Essex, and of Allhallows in London. He was honoured with the degree of doctor in divinity. He died at a very advanced age at Croydon in Surrey, in June 1572. Different accounts are given of his character, but the main part is given of his adulator, whilst he led a single life; but Pitts, the papist, affirms us that he directed his labors to the service of religion, and employed his time in reading and writing the lives of the Saints. These accounts, however, are not altogether incompatible. As an imitator of English literature, his merits are acknowledged; and his industry in enriching our language with many translations, written in a style more pure and fluent than that of his contemporaries, entitles him to grateful commemoration. Some of the principal of his works of which there is no complete catalogue, are the "Miferum Curium," or "Eclogues on the Miseries of Courtiers," compiled by Aeaeus Silvius; the "Eclogues of Baptist Mutlum;" the "Calle de Labour," from the French; a treatise "Of Virtues," by Mancini; several "Lives of Saints;" the "Jugurnate war" of Sallust; a "Treatise against Skelton," who was poet laureat, and a great enemy to priests; and the most popular of all his works, the "Navis Stultifera" or "Ship of Fools," which is a fine translation, but not very considerable, the mythology of a word of the same tle, by Schaffan Brantius; this is a satirical work, adorned with many pictures printed from wooden cuts; it passed through several editions, and was first printed at London by Richard Pynson, in 1509, in small folio, again in 1519, and in 4to. in 1570. Gen. Dict. Biotic.

BARCLAY, William, a learned civilian, was born in Aberdeenshire in 1531, and defended from one of the best families in Scotland. After the captivity of Mary queen of Scots, by whom he was favoured, he retired to France about the year 1572, and then by close application became a proficient in the knowledge of the civil law, so that he obtained a professorship in that science in the university of Ponta-
Pontamouillon, founded by the duke of Lorrain; he was also appointed by this duke count of late, and master of parks. In 1581, he married a lady of Lorrain, by whom he had a son, who was the cause of his contest with the Jaffetas, by whose influence he was reduced to the necessity of quitting Lorrain. He then came to England, and was offered a place in the council of James I., with a considerable pension, on condition of his embracing the established religion; but declining the offer, he returned to France, and accepted the professorship of civil law in the university of Angers, where he taught for some time with reputation. Here he died some time in 1605, according to others in 1609, or 1611. The chief of his works are "De Regno et Regali potestate," aduersus Barberana, &c.; published at Paris in 1601; "De potestate Papae, et quatenus in reges et principes seculares et imperium habet," Francof. 1609, 1615, 1629. Hannov. 1611, 1612, 1610. Lond. in English, in 1611, 1612; "A Commentary upon the title of the Papacy, de rebus ereditis et de jurisdiccione," Paris, 1605, 1606; and "Prefatia in vitam Agricultor." Paris, 1599, 2 vols. 8vo. Gen. Dict. Biog. Brit.

Barclay, John, the son of the preceding, was born at Pontamouillon in 1582, and distinguished himself betwixt as a proficient in polite literature. The Jaffetas wished him to enter into their society; but his father incurred their resentment by preventing it, and taking him to England, at the beginning of the reign of James I. He had already, viz., in 1601, published a commentary on the Thebaid of Statius. He also presented to James, a Latin poem upon his coronation; and in 1603, published the first part of his "Satiricon Euphormionis," which was dedicated to the king. He accompanied his father to Angers, with whom he continued till the death of the latter, and then returned to Paris. In 1606, he came over to England, where he obtained considerable employments under King James, and was made gentleman of the bed-chamber. He is said to have affiliated this prince in a controversial work, which occasioned some unfounded suspicions of his orthodoxy. Having finished his "Euphormion," he published an apology for it in 1610. Upon his return to Paris, he printed in 1612, a work intitled "Pietas," being a vindication of a performance of his father against the power arrogated by the popes over crowned heads, which had been attacked by Bellarmine. Nevertheless, he was invited to Rome by Paul IV., and refused there during the latter part of his life, cared for by Bellarmine, and poffeeding some lucrative employments, in return for which he wrote a work of controversy, intitled, "Parens ad Sectarios." While he was employed in superintending the first edition of his principal work, intitled the "Argenis," he died of the Plague at Rome, in 1621. The disputation of Barclay was of a melancholy cast; his mornings were uninterruptedly employed in study, and the afternoons were devoted to his garden. His reputation, both as a scholar and a writer, was extremely high in his own times; but his works were not of a nature, calculated to command lasting attention. His Latin style was much admired by some, and severely cenfrured by others. Petronius was his model, but he somewhat partakes of the bard afflication of Apuleius in his prose, and of the bombast of Lucian in his verse. His "Euphormion," and "Argenis," both works of invention, palled through several editions in various languages. The latter is a kind of political allegory, exhibiting a picture of the vices and revolutions of courts, with real characters under fictitious names. It displays great ingenuity and learning, and abounds with lively imagery and elevated sentiments, but with too much parade. It was read with avidity whilst the subjects were recent; and a translation of it in English by a lady appeared in 1772, without attracting much notice. Gen. Dict. Biog. Brit.

Barclay, Robert, the famous apologist for the Quakers, was the descendant of an ancient family in Scotland, and the son of colonel David Barclay of Mathers. He was born at Gordonstone in the shire of Murray, in 1648, whether his father had retired, after quitting the army; and was sent for education to his uncle at Paris, who was at that time principal of the Scots college. Pains were taken to profyle him to the catholic religion; and he acknowledged that they were not altogether unsuccess. He returned home, however, in his 17th year, and was distinguished by his accomplishments in literature, and particularly by his knowledge of the Latin and French languages. At home he extended his acquaintance, by diligent application, with the Greek and Hebrew; and being of a grave disposition, directed his inquiries towards theological subjects. His father, having in 1666 become a convert to Quakerism, was soon followed by his son; whose zeal, though generally under the control of a sedate temper and careful judgment, was not altogether free from enthusiasm; for he conceived himself obliged by divine command to pass through the streets of Aberdeen clothed in sackcloth and ashes, and he actually yielded to this impulse. But he served the cause, to which he was attached from conviction, much more effectually by his powers of reasoning in its defence. His first publication to this purpose, intitled "Truth cleared of calumnies," &c., was a reply to a work of W. Mitchell, a preacher near Aberdeen, and dated at his father's house at Urrie, in 1670. This was followed by an appendix and additional treatise, exhibiting a considerable portion of controversial acumen, but it had the effect of increasing his antagonist. In 1673 he published, with a view of conciliating the good opinion of Protestants, a systematic exposition of the doctrines of his sect, under the title of "A Catechism and Confession of Faith," approved of and agreed to by the general assembly of the Patriarchs, Prophets, and Apostles, Christ himself chief Speaker in and among them," &c. The design of this work was to prove, that Quakerism was the perfection of the reformed religion, and that Protestants, as they receded from it, were too inconsistent with themselves, and approached to Papery. His fundamental principle was, that the scriptures alone were to be regarded as the foundation of faith, and that Chirilians ought to receive no doctrines which were not capable of being proved by the express words of scripture. This work excited very general attention, and removed many prejudices that were entertained against the society. His next treatise, intitled "The Anarchy of the Cahters and other Libertines, the Hierarchy of the Romanists, and other pretended churches, equally refuted," &c., was intended to mark the distinction between the rationalists of his sect, and the enthusiasts; but some sentiments concerning church discipline, which it contained, involved him in disputes with some of his own brethren, and drew upon him attacks from some members of the university of Aberdeen, and from other quarters. He perfilled, however, in his endeavours for forming a clear, methodical, and rational system of Quakerism; and in the year 1675, he was diligently employed in compounding the most famous of all his writings, which is his "Apology for the true Christian divinity, as the same is held forth and preached by the people in scorn called Quakers." This was introduced by his "Theses Theologica," written in various languages, and addressed to the clergy of all denominations throughout Europe, requiring their examination.

Vol. III.
tion and judgment. Two copies of the "Apology" were transmitted to each of the ministers pontifical then assembled at the congress of Nimegen. It was printed in 1676, at Amsterdam; and two years after, the author published an English translation of it. It was also translated into other languages, and excited very general attention. The "Apology" is a learned, scholastic, methodical performance; and it is regarded as the first authority for the principles of the sect. The society derived considerable reputation from it; and whilst it contributed to remove prejudices against this sect both at home and abroad, it gave them a respectable rank among the reformed churches. The dedication is no less remarkable than the apology itself. It is addressed to King Charles II.; and speaks to him in plain and forcible a manner respecting the events of his own life, and pleads the cause of religion, and of the author's own society, with such a main spirit, that it has ever been admired as a model in its kind. Let the following passage serve as a specimen: "Thou hast called of prosperity and adversity; thou knowest what it is to be banished thy native country, to be over-raked as well as to rule and sit upon the throne; and being oppressed, thou hast reason to know how hateful the oppressor is both to God and man." This address did not avail, as Voltaire affirms, to restrain the perfecution which then raged against the Quakers; for Robert Barclay himself, after his return from Holland and Germany, which he visited in company with the famous William Penn, was, in 1677, imprisoned in Aberdeen, together with his father and many other Quakers, at the instigation of Sharp archbishop of St. Andrew's, with whom he remonstrated by an excellent letter on the occasion. By the interposition of Elizabeth the princes's palatine of Rhine, who respected the Quakers and corresponded with both Penn and Barclay, he was soon liberated; and he even acquired the favour of the court, so that in 1679, he obtained a royal charter for erecting his lands at Urine into a free barony. In 1682, he was elected governor of Coft Jerey, in North America, by the proprietors of the province; but he declined accepting the appointment, and was satisfied with naming a deputy-governor. Whilst he was in prison at Aberdeen, in 1677, he published a treatise on "Universal Love," intended to shew that this principle prevailed more in his church than in any other. In the same year he addressed a Latin letter to all "the ambassadors and deputies of the Christian princes and states, met at Nimegen to consult the peace of Christendom," urging them to promote that good work, and pointing out the true causes of war, and its incomparability with Christian principles. He had also written, in 1676, a Latin letter concerning "the Possibility and Necessity of an inward and immediate Revelation," to Adrian Paets, a peron of distinction in Holland; and in 1686 this letter was translated into English and published. This was the last, and has by many members of the society, been reckoned among the most important of his performances. His time was very much occupied in journeys for the benefit of the society, with a view both of promulgating its doctrines and protecting its members from oppression. Barclay and Penn were on terms of intimacy with James II.; who, sensible that he and his party needed toleration, affected to be the great patron of liberty of conscience. The non-refuting principles of the Quakers in civil matters, might probably give him a predilection for their religious opinions above those of other Protestants. Barclay was engaged in a private conference with the king in the year 1688, just as the wind became fair for bringing over the prince of Orange, and on that occasion urged his majesty to make some concession for satisfying his people; but his advice was of no avail. Robert Barclay did not long survive the revolution. He died, after a short illness, in his house at Uri, in October 1692, in his forty-second year, leaving seven children, all of whom were living fifty years afterwards. The moral character of this eminent person corresponded to the great employment of his life, which was that of promoting what he conceived to be the cause of religious truth. He was amiable and respectable; nor did the gravity of his pursuits infuse any rigour or fourness into his conversation and manners. He governed his house with great prudence and discretion, and preferred a serene mind under all the changes of his fortune. Biog. Brit. Gen. Biog.

BARCLAY Forts, in Geography, is the weft point of the entrance into English harbour, on the south side of the island of Antigua; the eal point also has a battery, from which it is distant only about 500 yards.

BARCONE, in Navigation, a short broad vessel, of a middle size, used in the Mediterranean for the carriage of corn, wood, salt, and other provisions, from one place to another.

BARDA, or Partha, in Geography, a town of Germany, in the circle of Upper Saxony and circle of Leipfick, 2 miles S.W. of Grimma.

BARDANA, in Botany. See Arctium.

BARDANA, in the Materia Medica. See Arctium Lappa.

BARDANE, in Entymology, a species of Curculio, of cyllindrical form, downy, greyish; anterior legs elongated. About the size of C. paraphillicus, and not unlike it in appearance. Inhabit Europe.

BARDARIOE, in Antiquity, were a kind of ancient guard attending the Greek emperors, armed with rods, wherewith they kept off the people from crowding too near the prince, when on horseback. Their captain, or commander, was denominated priminvigiris. The word was probably formed from the barda or housings on their horses.

BARDE. See Barfe.

BARDED, in Heraldry, is used in speaking of a horse that is caparisoned.

He bears fable, a cavalier d'or, the horse barded, argent.

BARDELL, in the Mango, denotes a faddle made in form of a great faddle, but only of cloth stuffed with straw, and tied tight down with packthread, without either leather, wood, or iron. Bardeles are not used in France; but in Italy they trot their colts with such faddles; and those who ride them are called evoladores, or fosenso.

BARDESAIMISTS, in Ecclesiastical History, a sect thus denominated from their leader, Bardeasan, a Syrian of Edessa in Mesopotamia, in the second century. Bardanes was a man of acute genius and profound erudition, and wrote several works which procured him reputation. He was eloquent in the Syriac language, and well acquainted with the Greek. His thirst for knowledge induced him to travel into the east, in order to converse with the brach- mans and other philosophers of that country. He was held in high estimation by Abgarus, who reigned in Edessa from the year 152 to 187. A work written by him, "upon Defliny," against Abyssus the astrologer, was valued by the ancients; and a fragment of it is quoted by Eusebius, in his Prep. Evang.

Bardeasen adopted the oriental philosophy concerning the two principles; maintaining that the supreme God is free from all evil and imperfection, and that he created the world and its inhabitants pure and incorrupt; that in
proceeds of time the prince of darkness, who is the fountain of all evil and misery, enticed men to sin; in consequence of which, the Supreme God permitted them to be dispenser of those ethereal bodies with which he had adorned them, and to fall into flagrath and gross bodies formed by the evil principle: and that Jesus descended from heaven, clothed not with a real but aerial body, in order to recover mankind from that body of corruption which they now carry about them; and that he will raise the obedient to mansions of felicity, clothed with aerial vehicles, or celestial bodies. It is said that Bardeus at length renounced the more chimerical part of his system. Eusebius denied that he ever returned to the Catholic faith. His facts fulfilled for a long time in Syria, to which his 150 hymns written in elegant Syriac very much contributed; as they also did to the propagation of his opinions. Mosheim's Ecc. Hist. vol. i. p. 220. Larbouër's Works, vol. ii. p. 299, &c.

BARDEWICK, in Geography, a town of Germany, in the circle of Lower Saxony, on the Ilmenau, supposed to be one of the most ancient towns in Germany. It was in a very prosperous state, and the see of a bishop in 1189, when Henry the Lion, duke of Saxony and Brunswick, took and razed it to the ground, because the inhabitants would not acknowledge him after he had been proffered by the emperor Frederick I. The bishopric was then removed to Verden; and the city of Luneburg received the advantages of trade and population: 4 miles N. of Luneburg.

BARDEWISCH, a town of Germany, in the circle of Weilphalia, and county of Detmold: 6 miles N. of Detmold.

BARDI, a town of Italy, in the Parmesan, seated on a rock near the small river Cono, and capital of a marquisate, to which it gives a name; 26 miles W. of Parma.

BARDIN, a town of Peru, in the province of Segedan, 30 miles W.S.W. of Zarang.

BARDIS, a town of Egypt, and residence of a sheik, whose authority extends a considerable way along the Nile; 6 miles south of Girga.

BARDISTAN, Cape, lies on the coast of Peru, in the Indian ocean. N. lat. 28° 4'. E. long. 52° 6'.

BARDONACHE, a town of Piedmont, in a valley, to which it gives name; 10 miles north of Sesana, and 6 W.N.W. of Exilles.

BARDO, a river of England, which runs into the Reid, 6 miles N.W. of Elliston, in Northumberland.

BARDIS, Bards, in Antiquity, ancient poets among the Gaus and Britons, who described and sung in verse the brave actions of the great men of their nation; with design to inculcate and recommend virtue, and even sometimes to put an end to the difference between armies at the point of engagement.

Bochart derives the word from parant, to sing. Camden agrees with Feilus, that bardus originally signifies a finger: and adds, that the word is pure British. Others derive the word from Bardus, a druid, the son of Dryis, and the fifth king of the Celts.

Amidst this uncertainty with regard to the etymology of the appellation barids or bard, we may add that feine have derived it from bar, which signifies fury, and which bears, without doubt, some analogy to that poetic fury or exalting passion which poets fancied themselves, or might feign to be inspired. Among the Welsh, we are told by others, bard is preferred as an indigenous term, having an abstruse significature, and denoting one that makes conspicuous, or caues to be revealed. By another

author we are informed that the word bard being a primitive noun, neither derived nor compounded, it can neither be traced to its root, nor resolved into its parts. It signified one who was a poet by his genius and profession, and who employed much of his time in composing and singing versets on various subjects and occasions.

The bard, it is said, differed from the druids, in that the latter were priests and teachers of the nation, but the former only poets and writers.

Larrey, Bodin, and Patquier, indeed, will have the bards to have been priests, as well as philosophers: and Cluverius, orators too; but without much foundation in antiquity. Strabo divides the sects of philosophers among the Gauls and Britons into three, viz. the druids, bards, and exets. The bards, adds he, are the fingers and poets; the evets, the priests and natural philosophers; and the druids, to natural philosophy add also the moral. Horace however reduces them to two facts, viz. bards and druids; others to one, and make a druid a general name, comprehending all the others. Cluverius will have it, that there were bards also among the ancient Germans; because Tacitus makes mention of their songs and poems, which contained their history. Some have distributed the ancient British poets into two classes; the first class comprehending their sacred poets, who composed and sung their religious hymns, and were called in Greek Eubiates, in Latin Pateris, and in their own language Faids; the second comprehending all their secular poets, who sung of the battles of the heroes, or the heaving breasts of love, according to the description of Ossian, and they were called bards. The principal bards of these bards was to celebrate the praises of the gods and departed heroes, in odes and verses, and to sing them to their harps, at their religious assemblies, public festivals, and private entertainments. These men were, in fact, the heralds, the chronologers, and the historians, as well as the poets of the land, for they kept up the memory of illustrious transactions, and, by their compositions, which tradition handed down to posterity, they transmitted from age to age the names and characters of patriot and warriors. It is remarkable that such a class of persons fubfisted in almost all nations. They derive their origin from remote antiquity, and were ever held in high estimation. Mankind have been early led to poetical compositions. Agreeable sounds strike at first every ear, but poetry was necessary to give those sounds a lasting effect. Verfe has therefore been made use of to preserve the memory of remarkable events and great actions. The religious ceremonies of nations, their manners, and their labour, were also recorded in numbers. Hence it was that Greece could boast of a Homer, a Hufiod, and of other poets, some ages before an historian had written in prose. Amongst the Gauls also, and other Celtic nations, there were poems composed on various subjects from the earliest ages. Diodorus Siculus is the first author among the ancients, who mentions the bards as the composers of verse; which they sung to the sound of an instrument not unlike a lyre (1. v. § 31.). Annemarried Marcellinus informs us (1. xii. c. 9.), that the bards celebrated the brave actions of illustrious men in heroic poems, which they sung to the sweet sounds of the lyre. This account of these Greek and Latin writers is confirmed by the general train and by many particular passages of the poems of Ossian. "Beneath his own tree, at intervals, each bard sat down with his harp; they moved the long line, and sang the song, each to the chief he loved." But this union between poetry and music did not flourish very long, in its greatest influence, perhaps, in any country. "The musicus soon became very numerous, and those of them who had not a genius for composing"
posing verses of their own, affixed in singing the verses of others to the music of their harps. Many of those songsters, or parasites (as Athenæus, i. vi. c. 12. calls them), which the Celtic princes took with them when they went to war, were mere musicians, and the songs which they sung were composed by those among them who had a poetical genius, and were called bards. Ossian, however, excelled as much both in vocal and instrumental music as he did in poetry, and he seems to have had no idea of playing on an instrument without singing at the same time. Whenever his bards touch the string, they always raise the song.

The bards constituted one of the most respected orders of men in the ancient Brititish states; and many of the greatest kings, heroes and heroes, esteemed it an honour to be enrolled in this order. They enjoyed, by law and custom, many honourable distinctions and valuable privileges. Kings and princes made choice of bards to be their bosom-friends and constant companions: indulged them with the greatest familiarity, and gave them the most flattering titles. Their persons were held sacred and inviolable; and the most cruel and bloody tyrants dared not to offer them any injury. The bards, as well as the druids, were exempted from taxes and military services, even in times of the greatest danger; and when they attended their patrons in the field, to record and celebrate their great actions, they had a guard assigned them for their protection. At all festivals and public assemblies they were seated near the person of the king or chieftain, and sometimes even above the greatest nobility and chief officers of the court. Nor was the profession of the bard less lucrative than honourable. For, besides the valuable presents which they occasionally received from their patrons, when they gave them uncommon pleasure by their performances, they had estates in land allotted for their support. Nay, so great was the estimation which the princes of these times entertained for the persons of their poets, and so highly were they charmed and delighted with their tuneful strains, that they sometimes pardoned even their capital crimes for a song. It may be reasonably supposed that a profession, which was so honourable and advantageous, and to which were annexed so many flattering distinctions and defirable immunities, would not be defected. Accordingly, the accounts we have of the numbers of the bards in some countries, particularly in Ireland, are hardly credible. In the poems of Ossian we often read of 100 bards belonging to one prince, singing and playing in concert for his entertainment. Every chief bard, who was called Allah Redan, or doctor in poetry, was allowed to have 50 attendants inferior in rank to his person; and every bard of the second rank was allowed a retinue of 15 poetical disciples. But it is probable that the bards of Britain and Ireland were not so numerous at an early period as they became afterwards; nor were they then guilty of those crimes by which they at length forfeited the public favour. In this most ancient period, the British bards seem to have been in general men of genius and virtue, who merited the honours which they enjoyed. Though the ancient Britons of the southern parts of this island had originally the same taste and genius for poetry with those in the north, yet none of their poetical compositions have been preferred; and this may be easily accounted for. After the provincial Britons had submitted quietly to the Roman government, yielded up their arms, and had left their free and martial spirit, they could take little pleasure in hearing or repeating the songs of their bards, in honour of the glorious achievements of their brave ancestors. The Romans too, if they did not practise the same barbarous policy which was long after practised by Edward I. of putting the bards to death, would at least discourage them, and discontertauence the repetition of their poems for very obvious reasons. These sons of the fong being thus persecuted by their conquerors, and neglected by their countrymen, either abandoned their country or their profession; and their songs, being no longer heard, were soon forgotten. But so natural was a taste for poetry to the original inhabitants of this island, that it was not quite destroyed by their long subjection to the Romans, but appeared again in the poetry of the provincial Britons, as soon as they recovered their martial spirit, and became a free, brave, and independent people. Nennius, who wrote in the ninth century, and in the reign of prince Merlyn, is the first of the British historians who mentions the bards. He says, that Talhaic was famous for poetry; that Aneruni and Talcin, Llywarth-hen and Chian, flourished in the 5th century. Of these bards, the works only of three are extant: those of Aneruni, Talcin, and Llywarth-hen. Besides the bards already mentioned, there were others who flourished during this period; of whom the most eminent was Mersed Wyllt, who composed a poem called Affallenau, or the orchard. From the fifth to the tenth century it is difficult to meet with any of the writings of the bards, owing probably to the devastations of war, and to the civil diificulties among the Welsh.

Such was the respect in which the bards were held, that by a law of Howel Dha, whoever struck any one of this order must compound for the offence by paying to the party aggrieved one-fourth more than was necessary to be paid to any other person of the same degree.

The election of the bards was made every year, in an assembly of the princes and chieftains of the country, in which they were all summoned, and the most eminent took a prominent part. From the ninth to the eleventh century it is difficult to meet with any of the writings of the bards, owing probably to the devastations of war, and to the civil diificulties among the Welsh.

It appears, upon a close examination of its principles, that one of the primary intentions of bardism was, that it should be a regular system for preserving authenticated records and various kinds of knowledge in the national memory, as it were, by means of oral tradition. And, in order that nothing should have currency without due confirmation, whatever was intended to be received into such a public record, whether the historical and apothecary etc., or the dietary fong, was always laid before the grand meetings. There it was discussed with the most scrutinizing severity; if it was objected, it was re-considered at the second meeting; if then approved of, it was referred to the third meeting; and being approved of by that, it was ratified or confirmed; otherwise it was re-
BARDS.

ferred to the triennial supreme convention for ultimate consideration. At this national meeting, all that had been confirmed at the provincial assemblies were also received; and the disciples, who then attended from every province, were enjoined to learn them, in order that they might become as widely diffused as possible. What was thus formally sanctioned was to be recited for ever afterwards, annually at least, in addition to the former bardic traditions, in the secondary meetings of districts, and also at one or other of the four grand meetings. Such being the bardic establishment, by which tradition became formed into a well-combined science, we may rely on its triads for the best illustration of its principles.

The three cultivators of song and imagination among the nation of the Cymry were Gaway or Cadwallon, who was the first in the world that composed poetry; Ithu the mighty, who first applied poetry to prefer memorials and composition; and Tydalin Tal Auen, or Tydalin father of the muse, who first reduced poetry to an art, and established rules for composition. And from what those three persons executed, originated bards and bardism, as constituted with privilege and custom by the three institutional bards, namely Plemwyn, Alun, and Gaven. They established the privileges and customs which appertain to bards and bardism, and therefore they are called the three institutors. Nevertheless there were bards and bardism before their time; but they were not under the regulation of inviolable transit; and they had neither privileges nor customs, except what were obtained through civility and courtesy, under the protection of the country and nation, before the time of these three. Some say that they were contemporary with Prydain, son of the Great; but according to others, they lived in the time of Dywern Mael Mudd, his son, who, in some old books is called Drenwards, son of Prydain. For a further account of these institutional bards, and of the triads that exhibit their character, office, and privileges, and that illustrate their theology, we must refer the curious who wish to find further information on this subject, to Williams's Poems, lyric and pastoral, in 2 vols. 8vo. London, 1794; and to Owen's Heroic Elegies of Llywarch-Flach, in 1 vol. 8vo. London, 1792. According to the latter of those writers, the bards were divided into Bards Brion, who were the civil magistrates or judges; and Bards Druid, who were the priests of the community.

From the triads above referred to the reader may deduce a correct outline of bardism; and as to the detail of its various parts, he may be surfeited to be told that they are still preserved in various memorials of the ancient Britons, and in the memory of its initiates; though it is generally suppos'd that this extraordinary system, known to the world under the name of Druidism, has perished about fifteen hundred years past, except the few hints given of it by Greek and Roman writers. Lo! it certainly would have been but for its extraordinary means and precaution for self-preservation; especially in the middle ages, when it had to withstand the persecutions of the popish church in the fulness of its power. Here it may be worthy to remark that bardism contains a great many things to induce a conviction of its being the parent of free-masonry; and some of the principles taught in both are the same in expression; and indeed it is very remarkable, that artifan, or mason, is exactly the meaning of coine, or ovate, the name of the third class of bards; and in this character only could the bards meet under cover. Free-masons do so now; but they preserve a traditioinary memorial of their meeting annually on the tops of their highest hills, and in the bottoms of the lowest vales, and when the sun was in its due meridian. Thus bardism, whose principles were to be diffused in the face of the sun and in the eye of the light, for the sake of truth and self-preservation, had the means of becoming even more secret than masonry veiled in the darkens of night.

There were three different classes of this order in Wales; the first was called "Diddlys," and they were the compoers of verbs and odes in various measure; they were likewise the recorders of the arms of the Welsh chieftains, and the repositories also of the genealogies of families. This class was accounted the most honourable, and was high in the public estimation. The second class, called "Mindreds," were performers upon instruments, chiefly the harp and the cornu. The third were those who sang to musical instruments in general, and were called "DatgenGWauad/"

The talents of the Welsh bards were not solely employed in preferring the defects of families, in the praise of heroes, or in recording their illustrious actions; they sometimes in plaintive numbers mourned over the tomb of the fallen warrior.

When tyranny erected its banner in Wales, by the cruel policy of Edward in the massacre of the bards, that ancient feast of music and poetry was defeated by the muffs, and consequently was deprived of those fascinating arts which softened, at the same time that they invigorated, the genius of the people. During the spirited, and for a while the prosperous, insurrection of Owen Glendwrwy, the muffs revived their native seats, encouraged by the munificence of that leader, and animated by the transitory ray which had dawned upon freedom. When the Welsh had made the last effort for their expiring freedom, they sunk into a state of slavery the most deep and severe. The bards were prohibited by law from making their annual progress, and from holding public assemblies; which privileges were called by the natives "clera" and "cymhortha." During this period, and the contest between the house of York and Lancaster, the genius of poetry was nearly extinguished, or was only employed in soothing the miseries of the times, by obscure predictions of more prosperous days. A brighter prospect opening on this nation in the reign of Henry VII. a series of bards arose from that time; and these bards, being supported in the families of the Welsh chieftains, ascertained and preferred their genealogies; and as the causes of resisting warlike exploits had ceased, they celebrated the civil virtues of their patrons, their magnanimity, their hospitable spirit, their talents, and the graces of their persons. They likewise, amidst other duties, held the honourable office of composing in elegy, on the death of the chieftain in whose family they resided, which was sung to the surviving relations in honour of the dead, reciting the noble families from which the deceased had sprung, and the great actions performed by himself or his ancestors.

Since the reign of queen Elizabeth, there has not been any regular assemblies of the bards. The motives to emulation having ceased, and the spirit of ancient freedom being extinguished, the poetic fire, for which the Welsh nation had been so renowned, gradually declined. But a spark of that ancient fire still remains in the genius of the Welsh, which, in the feasons of their felicity, breaks out into a singular kind of poetry, called "pennyli." Even at this day some vein of the ancient minstrelsy survives among the Welsh mountains. Numbers of persons assemble, and sit round the harp, singing alternately "pennyli," or flounces of ancient or modern compositions. Often, like the mosiari of Italy, they sing extempore verses; and a person conversant in this art readily produces a "pennyli" appropriate to the lait that was sung. Many have their memories stored with several hundreds, perhaps thousands of pennyli; some of which have always ready for answers to every subject that can be proposed, or if their recol-
Bards.

reconciliation should fail them, their invention supplies them with something pertinent and proper for the occasion.

Bards have been found in many countries; and continued in Ireland and Scotland, as well as in Wales, to our own days. The genealogical fonnets of the Irish bards are still the chief foundations of the ancient history of Ireland.

Spenzer, the poet, in his view of the rate of Ireland in the reign of queen Elizabeth, observes that he caused several compositions of the bards to be translated; and, surely, he adds, "they flavoured of sweet wit and good invention, but skilled not of the gobdy ornament of poetry; yet were they sprinkled with some pretty flowers of their natural device, which gave good grace and comeliness unto them; the which in great pity to see so abused, to the graceing of wickedness and vice, which with good usage would serve to adorn and beautify virtue."

The songs of the Irish bards, says Warton in his "History of English Poetry" (dift. i. vol. i.), are by some conceived to be strongly marked with the traces of Scaldic imagination; and these traces are believed to have survived among a species of poetical historians, whom they call "Tale-Tellers," supposed to be the descendants of the original Irish bards. The Irish historians inform us that St. Patrick, when he converted Ireland to the Christian faith, destroyed 500 volumes of the songs of the Irish bards. Such was their dignity in this country, that they were permitted to wear a robe of the same colour with that of the royal family. They were constantly summoned to a triennial festival; and the most approved songs delivered at this assembly were ordered to be preferred in the custody of the king's historian or antiquary. Many of these compositions are referred to by Keating, as the foundation of his history of Ireland. Ample estates were appropriated to them that they might live in a condition of independence and ease. The profession was hereditary; but when a bard died, his estate devolved not to his eldest son, but to such of his family as discovered the most distinguished talents for poetry and music. Every principal bard, as we have already observed, retained thirty of inferior note as his attendants; and a bard of the secondary class was followed by a retinue of fifteen. They seem to have been at their height in the year 558. None of their poems have been translated.

In the highlands of Scotland there are considerable remains of many of the compositions of their old bards still preserved. But the most genuine, entire, and valuable remains of the works of the ancient bards, and perhaps the noblest specimen of uncultivated genius, are the poems of Ossian, the son of Fingal, a king of the Highlands of Scotland, who flourished in the second or third century, lately collected by Mr. Macpherson, and by him translated from the Erse or Gaelic language into English. Dr. Johnson, indeed, has suggested his doubts concerning the existence of any such ancient MSS. as those from which the poems of Ossian have been translated. But this is not a place for discoursing this subject of controversy. Admitting, however, their genuineness upon the whole, whatever additions may have been made to them, they afford an admirable specimen of what might be the conceptions of ancient bards. These poems, says Warton (ubi supra), notwithstanding the difference between the Gothic and the Celtic rituals, contain many valuable vestiges of Scandinavian superstition. The allusions in the songs of Ossian to spirits who preclude over the different parts, and direct the various operations of nature, who feed serpents over the deep, and rejoice in the pleasures of the shipwrecked mariner, who call down lightning to blast the forest or cleave the rock, and diffuse invisibly a beneficence among the people, beautifully conducted and heightened under the skillful hand of a master bard, entirely correspond with the Runic system, and breathe the spirit of its poetry. Had Ossian found it convenient to have introduced religion into his compositions, not only a new source had been opened to the sublime, in deferring the rites of sacrifice, the horrors of incantation, the solemn invocations of infernal beings, and the like dreadful superstitions, but probably many stronger and more characteristic evidences would have appeared of his knowledge of the imagery of Scandinavian poets.

The remains of Taliemon, and other Welsh poets, assist us in forming a competent judgment upon this subject. See Evans's Dissertation de Bards. Josèe's Historical and Poetical Relics of the Welsh Bards.

It is not improbable, says Warton (ubi supra,) that the Welsh bards might have been acquainted with the Scandinavian Scaldi, at least before their communication with Armorica. The bard's flourished most in those parts of Britain which most strongly retained their native Celtic character. The prodigy of the Welsh bards depended much on alliteration; hence they seem to have paid an attention to the Scaldic verification. The Islan~ic poets are said to have carried alliteration to the highest pitch of exactness in their earliest periods; whereas the Welsh bards of the fifth century used it but sparingly, and in an imperfect degree: from this circumstance we may deduce a proof of imitation, or at least of emulation. There are, moreover, strong traces of conformity between the manners of the two nations. Befides, the Scandinavian Scaldi were well known in Ireland; and there is sufficient evidence to prove that the Welch bards were early connected with the Irish. Even so late as the eleventh century, the practice continued among the Welch bards of receiving instructions in the bardic profession from Ireland. The Welch bards were reformed and regulated by Gryfynrh ap Conan, king of Wales, in the year 1078. At the same time he brought over with him from Ireland many Irish bards for the information and improvement of the Welch. In Ireland, to kill a bard was highly criminal; and to seize his estate, even for the public service and in time of national diftre{s, was deemed an act of sacrilege. Thus, in the old Welsh laws, whoever even slightly injured a bard, was to be fined 6 cows and 120 pence. The murderer of a bard was to be fined 126 cows. Moreover, an intercourse was necessarily produced between the Welsh and Scandinavians from the practical irritations of the latter. It may be added, that the Welsh, although living in a separate and detached situation, and so strongly prejudiced in favour of their own natures, yet from neighbourhood and unavoidable communications of various kinds, might have imbibed the ideas of the Scandinavian bards from the Saxons and Danes, after those nations had occupied and overthrown all the other parts of our island. (See Scalds.) The effect of an intercourse with Armorica is perceived in the composition of those Welsh bards who flourished after the native vein of British fable had been tainted by the "fairy tales" which had been propagated by the Arabians in Armorica, and which the Welsh had received from their connection with that province of Gaul. It is easy to collect from the Welsh odes, written after the tenth century, many signatures of this exotic imagery. See Scandinavia, and Armorica.

BARDSEY-Isle, in Geography, an island of Wales, called in Welch Ty Tisudd, or the island in the current, from the fierce current which runs between it and the main land; and Bardsey, probably from the bards who retired here. It forms the north point of Cardigan bay, and is separated opposite to it, within the county of Caernarvon. At Aberdaron bay there is good anchorage; but the entrance for large ships is very difficult. It was to this place that Dubitius, arch-
archbishop of Caerleon, retired after he had resigned his see to St. David, and here he is said to have died in 612. Baref
sen Abbey, of which the remains are considerably, was found-
ed in the year 516. A singular oratory belonging to it, con-
fined of a long arched edifice, with an inhabited stone
altar near the cell end. The island forms a remarkably fertile
and well cultivated plan of about two miles in compass. It
contains a few inhabitants, and is rented from lord Newbo-
rough. It was granted by Edward VI. to his uncle sir
Thomas Seymour, and after his death to the earl of War-
wick. The late sir John Wynt purchased it from the late Rev.
Dr. Wilton of Newark. It is 10 leagues N.E. by
N. of Caernarvon bar, and 12 leagues N. by W. of Holyhead
in the isle of Anglesea, N. lat. 52° 58'. W. long. 5° 5'.

BARDSTOWN, a town of Kentucky, in the United
States of North America, and chief place of the county of
Nelson, on the Beech Fork river; about 25 miles from the Ohio,
N. lat. 37° 48'. W. long. 86° 13' 30'.

BARLETT, or Baruth, a small town of Germany, in the
duchy of Pomerania, situated in a small bay on the Baltic,
fix leagues west from Stralsund. It belongs to Sweden.
N. lat. 54° 20'. E. long. 13° 20'.

BARDUHITZ, or Parantitz, a town of Bohemia, in
the circle of Chrudim, celebrated for its manufactures;
seated on the Elbe; fix miles north of Chrudim.

BARE, in a general sense, signifies not covered. Hence
we say bare-headed, bare-footed, &c.

The Roman women, in times of public distress and mourn-
ing, went bare-headed, with their hair loofe.

Among Greeks, Romans, and Barbarians, we find a
feal called nudipedalia, at which perfons were to attend
bare-footed.

The Abyssinians never enter their churches but bare-
footed; not on account of Moses, who was commanded to
put off his shoes on mount Sinai, but in reverence of the place;
as is also done by them in entering the palaces of
kings and great men.

Sagittarius has a dissertation on those who went bare-
footed among the ancients, "De Nudipedalibus Veterum;" in
which he treats of such as went bare-footed in journeys or
otherwise, either out of choice or necessity; also of bare-
footed religious mourners and penitents, who went bare-
footed; and, lastly, of the leviti.

Bare, in respect of Manufacture. A cloth is said to be
bare or naked when the nap is too short, as having been
flown too near, or not being sufficiently covered with wool
by the teazed.

Bare is also used for a sort of bowling ground, not cov-
ered with green sward.

Bare-Foot Carmelites, and Augustines, are religious
of the order of St. Carmel, and St. Augufin, who go
without shoes like the Capuchins.

There are also bare-foot fathers of mercy. Formerly
there were bare-foot Dominicans and bare-foot runs of the
order of St. Augufin.

Bare-Feet Tritonians. See Tritonian.

Bare-Poles, under, in Sea Language, expresses the state
of a ship, when the has no sail set.

Bare-Pump. See Pump.

Bare, in Geography, an island in the Southern Pacific
ocean, near the east coast of New Ireland. It is high land,
not fertile, but inhabited; sittuate in S. lat. 39° 57', and
88° W. from cape Kidnappers.

Bare Haven, lies on the coast of Nova Scotia, in North
America, about three leagues S.W. from cape Canoe. It
is sheltered by an island off the point called White point.

BAREA, in Ancient Geography, a town of Spain,
upon the Iberian sea, in the country of the Baftuli. Pro-
lemly.

BAREE, in Geography, a province of Hindooftan, in the
country of Lohore, between the rivers Raurave, Beyah,
and Setclelge.

BAREGE Waters, in the Materia Medica, are cele-
brated thermal waters, situated in and near the village of
Barego, on the French side of the Pyrenees, at the foot of
thee lofty mountains. There are four principal hot springs
in this place, which differ, however, very considerably in tem-
perature, the highest being about 120 Fahr. and the lowest
about 73°. This variety of heat gives every convenience,
for bathing, drinking, and topical application. Chemical
analysis shews in this water a quantity of sulphur, in the
form of sulphated hydrogen, united to a small portion of
foda, a little common salt, and a kind of limy bituminous
matter. The sulphur and the soda, together with the
heat, may be considered as the active ingredients, but the
quantity of them is very small; as the water scarcely ex-
ceeds distilled water in specific gravity.

The waters of Barege are remarkable for a smooth foamy
feel, and they give supplenees and smoothness even to dead
skin that is immersed in them. They are used chiefly as a
difcoutent and detergent bath, in revolting indolent tumours
and rigidity of the joints left by gouty or rheumatic affec-
tions. They are also of great advantage in cutaneous dif-
fusees. Internally taken, the water gives relief in disorders
of the stomach, heartburn, indigiflon, colic, and also in
several calculous affections of the urinary organs. Saunders
on Mineral Waters.

BARETH, Bareuth, or Bayreuth, in Geography,
a town of Germany, in Franconia, in the margravate of
Culmbach. It is the capital of the principality, and often
called the principality of Bareuth. Its palace, which was
burnt down in the year 1753, was again rebuilt in a beauti-
ful style. It has one Calvinist and two Lutheran churches, a
Roman Catholic chapel, a public school, a foundling ho-
spital, and an academy, founded in 1722 by the margrave Fre-
deric, beides the college. In 1430, this town was burnt
down by the Hufites. It belonged to a prince of the house
of Brandenburg, the laft of whom dying in 1782, it descend-
ed to the king of Prufia. Near the Fichtelburg, Bareuth
produces a variety of beautiful marbles, and some curious
minerals. The principality of Bareuth is also known by
the name of Culmbach; and with Onolbach, forms the chief
power in Franconia, now annexed to the sovereignty of
Prufia. N. lat. 50° 15'. E. long. 11° 50'.

BARELY, a town of Hindooftan, in the province of
Oude; 41 miles S.S.E. of Lucknow.

BAREN, a river of Germany, which runs into the Roer,
near Schwert, in the county of Marec, and circle of Weil-
phalia.

BAREN, a town of Swifferland, in the Valais, 25 miles
call of Sion.

BARENA, in Ancient Geography, a town of Asia, in

BARENFLELS, in Geography, a town of Germany, in
the circle of Upper Saxon, and county of Erzgeburg, two
miles west of Altenberg.

BARENEST; or BERNSTEIN, a town of Germany,
in the circle of Upper Saxon, and margravate of Meifen,
17 miles south of Dresden.

BARENT, DIETERICK, in Biography, a painter of
history and portrait, was born at Amsterdam in 1534; and
having received early instruction from his father, traveled to
Venice, where he was admitted into the school of Titian,
and became the favourite disciple of that inimitable ma-

BARETTI, Joseph, in Biography, was the son of an architect of reputation, and born at Turin about the year 1716. He received a good education, but squandered his patrimony in gaming. Being of a rambling and defultry disposition, he was frequently reduced, notwithstanding his talents and literary character, to circumstances of distress. In 1748, he was employed at Venice in teaching the Italian language to some English gentlemen; and in 1750, at the mitigation of Lord Charlemont, he visited England, which was the place of his future residence. Possessing a wonderful facility in acquiring the knowledge of languages, as well as a critical acquaintance with his own, his talents were well adapted to the profession of a teacher of languages, in which he engaged. In 1753 he wrote a treatise in English, which was "A Defence of the Poetry of his native country against the cen- sures of Voltaire." About this time an acquaintance commenced between Baretti and Dr. Johnson, which was kind and cordial on the part of the latter, and respectful in the highest degree on the part of the former. As he had acquired reputation by some works which he had published on the Italian language and literature, he availed himself of his friend's English dictionary to compile a dictionary of the Italian and English languages, which first appeared in 1760, and which maintains its superiority over all other works of the same kind. In this year he visited his native country, with some prospects of preferment, in which he was disappointed; but on his arrival he published at Venice a periodical work, intitled "Peulch Literatur," under the character of an old coining folder who was returned to his country after long absence. His criticisms, however, in this work, which met with great success, were so severe, that he was obliged to leave the country; and after an absence of six years, he returned through Spain and Portugal to England. In 1768 he published "An Account of the Manners and Customs of Italy," intended chiefly as a reply to the severe criticisms of Mr. S. Sharp, the surgeon, in his "Letters from Italy." By Dr. Johnson he was introduced into the family of Thrale both as a teacher and a literary guest. In 1769, he visited Spain, probably intending to complete his account of a tour in that country. Soon after his return, an accident occurred, which was followed by various disagreeable consequences. Having engaged in an angry altercation with a woman of the town in the Hay-market, he was accosted by three men, who insulted and jollied him. Alarmed for his life, Baretti took out of his pocket a French dexter knife, and attacked one of the assailants; and unfortunately pursuing the contest and repeating the blows, he inflicted wounds which proved fatal. He was arrested and tried for murder at the Old Bailey. In this trial the public were much interested; and a number of men of the first literary eminence appeared to bear testimony to Baretti's character; among whom were Johnson, Burke, Garrick, Goldsmith, Reynolds, and Beaucour. The event was the acquittal of Baretti; but the charge very materially affected his reputation. In 1770 he published his "Journey from London to Genoa, through England, Portugal, Spain, and France," 4 vols. 8vo., which was deferentially well received; and he continued publishing introductory works for the use of students in the Italian and some other modern languages. Although he had been demilitated in the family of Mr. Thrale, he left it in 1776, in difficult, and by this sudden flirt of whim or ill-humour, involved the latter part of his life in many inconveniences and difficulties. His attempt, in 1779, for introducing to the public a classical entertainment, which was the "Carmen Seculare" of Horace set to music, failed of success. Reduced to a state of precarious subsistence, he obtained under lord North's administration a pension from government of 80l. a year, but during the urgency of public wants this fell into arrear, and Baretti could scarcely relieve himself from absolute indigence. His last performance was published in 1785, and was intitled "Tolendron: Speeches to John Bowle about his edition of Don Quixote; together with some account of Spanish literature." Oppressed by anxiety and uneasiness of mind, and with a constitution impaired by fits of the gout, he died on May 5th, 1789. Baretti, although he had a rough and somewhat cynical appearance, was formed for society, and his conversation was instructive particularly to young persons, with whom he had much intercourse. Having lived much in the world, and having had no opportunity in early life of acquiring fixed principles, he indulged a considerable laxness and freedom of opinion. However his integrity was unimpeached, his morals were pure, and his manners were correct. His charity had no bounds, and by the imprimatur with which he exercised it, he was himself involved in difficulties. His literary talents, though not of the highest order, were useful and agreeable. "I know no man," said Dr. Johnson to Bofwell, "who carries his head higher in conversation than Baretti; there are strong powers in his mind; he has not, indeed, many hooks, but with what hooks he has he grapples very forcibly." Bofwell's Life of Johnson. Europ. Mag. for 1789. Gen. Biol.

BARF, in Geography, a town of France, in the department of the Lower Pyrenees, and chief place of a canton in the district of Maulne, 5 miles S.E. of Maulne.

BARFE, in Laws, a fee of 20 pence, which every person acquitted of felony pays the gaoler.

BAREFLEUR, in Geography, a sea-port town of France, in the department of the Channel. It had formerly a good harbour and a considerable trade; but in consequence of neglect, the harbour is choked with sand, and the trade decayed. Cape Barseur is six leagues east from Cherbourg, in N. lat. 49° 40'. W. long. 1° 17'.

BARGA, a town of Italy, in the duchy of Tuscany, on the river Senchio, two leagues from Lucca.

BARGAIN, in a General Shape, a contract either for the sale, purchase, or exchange of a thing. The word is formed from the French bargaigner, to barter or haggle. He that sells is the bargainer, and he that buys the bargainee.

BARGAIN and SELL, in Law, is properly a contract made of
of manors, lands, and other things, transferring the property thereof from the bargainer to the bargainee, for a consideration in money: or, it is an instrument by which the property of lands and tenements is for valuable consideration granted and transferred from one person to another. It is called a real contract upon a valuable consideration, for palling of lands, tenements, and hereditaments, by deed indented and enrolled. 2 Inst. 672.

It is a good contract for land, and the see palles, though it be not laid in the deed, to have and to hold to him and his heirs, and though there be no livery and seisin given by the vendor, so it be by deed indented, sealed, and enrolled, either in the county where the land lies, or in one of the king's courts of record at Westminster, within six months after the date of the deed.

This manner of conveying lands was created and established by the 27 H. VIII. c. 10, which executes all sales raised; and as this introduced a more secret way of conveying than was known to the policy of the common law, therefore the enrolment of the deed of bargain and sale was made necessary by the 16th chapter of that statute. The objects of this provision evidently were, first, to enforce the contracting parties to ascertain the terms of the conveyance by reducing it into writing; secondly, to make the proof of it easy, by requiring their seals to it, and consequently the presence of a witnesse, and lastly, to prevent the frauds of secret conveyances, by substituting the more effectual notoriety of enrolment, for the more ancient one of livery. But the latter part of this provision, which, if it had not been evaded, would have introduced almost an universal register of conveyances of the freehold, in case of corporal hereditaments, was soon defeated by the invention of the conveyance by lease and release, which sprung from the omission to extend the statute to bargains and sales for terms of years: (See 8 Co. 92; 2 Ro. Abr. 204. 2 Inst. 671.) and the other parts of the statute were necessarily ineffectual in our courts of equity, because there were still left at liberty to compel the execution of the trusts of the freehold, though created without deed or writing. The inconveniences arising from this insufficiency of the statute of enrolments, are now in some measure prevented by 29 Car. II. c. 3, which provides against conveying any lands or hereditaments for more than three years, or declaring trusts of them, otherwise than by writing. 1 Inst. 48 a. n. 3. See Blackf. Com. vol. ii. p. 538. Jacob's Law Dict. by Tomlyn, Art. Bargain and Sale.

Bargains, in Co-operation, are of divers kinds: verbal, those made only by word of mouth, and giving earnest; written, those where the terms are entered in form on paper, &c.

At Amsterdam they distinguish three kinds of bargains.

Bargains, Conditional, for goods which the seller has not yet in his possession; but which he knows have been bought for him by his correspondents abroad, and which he obliges himself to deliver to the buyer, on their arrival, at the price and the conditions agreed on.

Bargains, Firm, those wherein the seller obliges himself to deliver to the buyer a certain quantity of goods, at the price and in the time agreed on.

Bargains, Option, those wherein a dealer obliges himself, in consideration of a premium received in hand, either to deliver or take a certain quantity of goods at a fixed price, and within a time limited; but with a liberty, nevertheless, of not delivering or not receiving them, if they think proper, upon forfeiture of their premium.

Bargains, Forehand, are those wherein goods are bought or sold, in order to be delivered at a certain time afterwards, some part of the price being advanced.

BARGASA, in Ancient Geography, a town of Asia, in Caria, seated at the bottom of the gulf called Ceramicus.

BARGAZAR Point, in Geography, a cape on the coast of Iceland. N. lat. 66° 18'. W. long. 16° 38'.

BARGE, in Navigation, a kind of flat, or pleasure-boat, or large luggage boat, used chiefly in the navigation of rivers which lead to great cities.

Barges are of various kinds, and acquire various names, according to the variety of their uses and frature: as,

A company's barge, A Severn barge, A rover barge, A ware barge, A royal barge, A land barge, A West-country barge.

A barge differs from a bark, as being smaller, and used only on rivers; whereas the latter goes out to sea.

There are also barges, belonging to men of war, serving to carry generals, admirals, and chief commanders.

Sailing barges are vessels with one mast, and sometimes a bowsprit. Those that have boom-fails, are rigged like sloops; but, having few hands on board, the boom and gaff are more easily loisted or topped, the power being increased by the addition of blocks. Sailing lighters or barges, with a spirit-mainail, rig with a spirits-yard at the head of thefail, hanging diagonally to the mast. Some large barges have vangs like a ship's mizen, and a down-hauler at the peak-end of the spirits-yard. Large barges have a foresail, jib, crossjack-yard, and top-sail, similar to sloops.

Barge, or Barges, in Geography, a town of Piedmont, in the district of the four Vallies, 71 miles south of Pinerolo.

Barg-Brun, in Ornithology, Buffon's name of the dusky nipe; foledapus fulva, Gmelin.

Barge Blanche, is likewise a name assigned by Buffon to the white avoet, recurvirostra alba, Gmelin.

Barge le Chatel, in Geography, a town of France, in the department of the Ain, and chief place of a canton in the district of Pont-de-Vaux, 4 leagues W.N.W. of Bourgen-Bresse. N. lat. 46° 19'. E. long. 4° 49'.

Barge-Couples, in Architecture, a beam mortised into another, to strengthen the building.

Barge-Course is used by workmen to signify a part of the tiling, which projects over the gable of a building, and is made up with mortar.

BARGEMON, in Geography, a town of France, in the department of the Var, and chief place of a canton in the district of Draguignan, 2 leagues N.W. of Draguignan. BARGEH, is used in some places of England for a steep horse-way up a hill.

It seems to come from the German bargt, a hill.

Barg-Master, Barner, or Bar-Master, in the Royal Mines, the steward or judge of the barghmote.

The word is formed of the German barg-meister, q. d. master of the mines.

The bar-master is to keep two great courts of bargmote yearly, and every week a small one, as occasion requires.

Barghmote, or Barmote, a court which takes cognizance of caufes and disputes between miners.

Some suppose it thus called from a bar, at which the suitors appear; others, with more probability, derive the word from the German barg, a mine.

By the custom of the mines, no perfon is to sue any miner for ore-debt, or for ore, or for any ground in variances, but only in the court of bargmote, on penalty of forfeiting the debt, and paying the charge at law.
BAR

BARGICAS, in Ancient Geography, a town of His-panic Tarraconensis, situated in the inner part of the country, and in the territory of the Vaccaens. Plutarch.

BARGIE, in Geography, the name of a borough in the southern part of the county of Wexford, province of Lein-ster, Ireland, which, with the adjoining one of Forth, was proxeoted by the followers of Earl Strongbow. The ling- uage is still understood to be a broken Saxonic, more like Flemish than English, and not one in a hundred knows any thang of Irish. "They are evidently," says Mr. Young, "a distinct people, and I could not but remark that their features and cult of countenance varied very much from the common native Irish. The girls and women are handsome, hav- ing much better features and complexions. Their industry is superior to that of their neighbours; and their better living and habitation are also distinctions not to be forgotten. The poor have all barley bread and pork, herrings, and potatoes. On the coast there is a considerable inherit of herrings." Both men and women wear straw hats, which give them a comic appearance. The inhabitants are reckoned more industrious and cleanly, and better farmers than in any other part of Ireland; but Mr. Young found their system very defective. The farms were in general from 20 to 60 acres at an average rent of a guinea per acre. The foil is light, and being extremely well tilled, produces large quantities of barley, Young's Tour, and Latecmy's Rambles through Ireland.

BARGOSA, in Ancient Geography, a town of Spain, which was the country of the philoporer Zarmanocheagaa, who committed himself to the flames in the presence of Augulus, according to Strabo.

BARGOTA, in Geography, a town in Spain, Na- varre, 6 leagues from Elfella.

BARGULIA, or BARGULIS, in Ancient Geography, a place of Ilyria, in the neighbourhood of the people deno- minated Parthini, which Philip ceded to the Romans by a treaty, 204 years before the vulgar era.

BARGUS, a river of Ilyria; both sides of which were inhabited by the Scordifis; it discharged itself into the Iber, according to Strabo. Phiny says, that a river of this name flowed into the Hebrus.

BARGUSI, an ancient people of Spain, to whom envoys were sent from Rome to solicit the Spaniards to take part with the Romans rather than with the Carthaginians. They inhabited the interior of Spain, on the other side of the Ebrus; and were subdued by Hannibal. Livy, l. xxi. 19, 27.

BARGUSIN, in Geography, a town of Siberia, in the province of Nerthinsk, in the government of Irkutsk, formerly an oisleg, now a circle-town, on the right bank of the river Bargusin, 20 versts above where it falls into the Bargusinian bay of the Baikal, 53° lat. 127° long. 524 versts north-east from Irkutsk. It is most remarkable on account of the baths in its district. They were discovered in a wakie region, at the distance of eighty versts from any habitation. M. Grand, surgeon to a regiment quartered in those parts, having successfully prescribed the use of these baths to sev- eral patients, M. Von Kitkha, the governor of Irkutsk, in 1779, caused some buildings to be erected there. They have proved of great benefit to persons afflicted with rheu- matism, fevers, phthisis, and other complaints of a like nature; there it is said to be a broken Saxon, more like its aboriginal tribe resembling that of rotten eggs, mixed with milk. It promotes perspiration, does not quench thirst, and may be drank in large portions. When boiled, it is of a very agreeable taste, and is particularly good with tea.

BARGYLA, BARGYLL, or BARGILE, in Ancient Geography, a town of Asa Minor, in Caria, near Jafes and Mundos. It is mentioned by Pliny, Strabo, and Pto- lemy. It was situated near the Meander, south of Miletus. M. d'Anville places it north-east of Halicarnassus, on the gulf called Iasius.

BARGYLYS, a mountain of Phocicia, on the confines of Syria, on the way towards Antiochene. It was situated north of Mount Libanus.

BARI-NAGASH, in Geography. See Baharna- ges.

BARI, a sea-port town of Italy, in the kingdom of Na- ples, on the coast of the Adriatic; once the capital of a province of the same name, and seat of an archbishop. It is well built, populous, and has a good trade. The harbour was almost destroyed by the Venetians; 120 miles. E.N.E. of Naples. N. lat. 41° 31'. E. long. 17° 45'. It contains, says Swinhurne, about 6000 people.

BARI, or Terra di Barri, a province of Naples, deriving its name from its capital. It is bounded on the north and north-east by the sea, on the coast and south-east by the prov- ince of Otranto, on the south by the Basilicata, and on the west and north-west by the Capitanata. It is about 62 miles long, and its mean breadth is rather more than 20 miles. It produces corn, wine, oil, cotton, linen, and fruits; and the coast is guarded against the corsairs by fixed fortresses. Its chief ports are Barletta, Trani, Barri, and Monfetta; its mountains are Sanazzo, Feronia, Monti, Lopulo, Franco, and St. Agodina; and its rivers are Olanto and Cane. The extent, according to Swinhurne, is 369,097 morgia, 5 morgie being equal to 4 English acres; and he states the number of its inhabitants to be 281,048. The city of Barri is the ancient Bariun; and coins struck by its principal magistrates still exist. The Lombards, Greeks, and Saracens disputed the possession of this city in the ninth century. In the tenth, it reëst to distinction on becoming the residence of the Greek catapan or viceroy, and a metropol-itan bishop. The book of constitutions, compiled for the juridical government of the province, and fill in the use, is a respectable voucher for the importance and policy of Bari, during the middle ages. About the year 1300, Bari became the scene of conspiracies and revolutions. Melo confederated against the Grecian emperor in this place; but it retained its subjection to the caliph, and was one of the last and foremost supports of his dominion. In 1067, Robert Guifard invaded it by sea and land, and en- closed it by a semicircle of ships joined together by chains and booms, in order to prevent its obtaining succours. This blockade lasted four years. Earl Roger afterwards joined his brother with a strong fleet, defeated the Imperial squadron sent for the relief of the city, and made its ad- miral prisoner; upon which Bari opened its gates to the conquerors. A citadel was erected by king Roger for re- cording the allegiance of this town, but it was hardly finished when Lotharius razed it to the ground. At this time, Bari was a populous and strong place. It was afterwards treated with great severity by William the Bad, who levelled the dwellings of the inhabitants who joined in the grand rebel- lion against him to the ground. The city, however, must have riven speedily out of its ruins, as the emperor Freder- ick reëstablished an annual fair here in 1235; but in 1248, he ordered the town to be destroyed, by way of punishing the inhabitants for treasonable practices. Bari frequently changed its proprietors, till it was settled by Alphonius the second upon the family of Sforza, in consideration of the marriage of his daughter Isabella with the duke of Milan. According to treaty, these estates became the property of Bona, queen of Poland, at whose death this duchy returned
BAR

to the crown, to which it has ever since remained annexed.

BARJAC, a town of France, in the department of the
Gard, and chief place of a canton, in the district of Alais. The
place contains 1373 and the canton 2280 inhabitants; the ter-
ritory includes 1074 kilometeres and 8 communes.

BARJAN, in *Agriculture*, a town of Alfis, in
Melopotamia. Polevny.

BARJARE, in Geography, a town of Peria, in
the province of Kerman, 15 leagues S.W. of Siogian.

BARJEI, or BARNACLE POINT, is the south-easterly part
of Wighthorpe's bay on the north-east coast of Antigua island,
and on the west side of the channel into Parham harbour.

BARILLA, or Barilha, is the term by which the
impure mineral alkali from the coasts of Spain and some
other parts of the Levant is known in commerce. That
from Alicant and the coasts of the province of Murcia
is the most esteemed. It is brought over in the form of hard
brown speckled porous mafles almost without smell, and
sailing strongly alkaline. It is procured by burning to ashes
several plants growing on the sea-shore of the species of
Salpila and Kali. For the particulars of this manufacture, see
Salpila. The term *Barilla* is also applied sometimes to *Kelk*, a much more impure soda, and sometimes,
though improperly, to *peas* in the plant containing
potash, the vegetable alkalis. See Carbonat of Soda.

BARILLARIUS, an ancient officer in monarchies and
great households, who had the care of the cafes and vealises
of wine, &c. in the cellars.

BARILLOVITZ, in Geography, a town of Croatia, on
the River Korana, 10 miles south of Carlstadt.

BARIN, a town of Asiatic Turkey, in the province of
Natolia; 12 miles south of Amasaiah.

BARING OF TREES, in *Agriculture*. See ABRUL-
ATION.

BARJOIS, in Geography, a town of France, in the
department of the Var, and chief place of a canton in the district of
Brignolles. The town is populous, and situated in a plea-
sant country; 9 leagues north of Toulon. The place
contains 3025 and the canton 8079 inhabitants; the territory
includes 250 Kilometeres and 11 communes. N. lat. 43° 38'.
E. long. 5° 23'.

BARQUISEMETO, a river of North America, in
the country of Terra Firma, which runs into the Oro-
noko.

BARISSOGLBSK, or Bogissoglbesk, a town newly
erected by Catharine II. in the province of Yaroslav, is
situated on the Volga, 57° 39' lat. 57° 6' longit. has 4
brick, and 417 wooden houses, 2076 inhabitants, and a
brick church. The trade of this town consists in the pro-
duction of the fishery and several manufacturies of hardware;
chiefly pots and kettles. The home and foreign trade to-
gether amount nearly to 60,000 rubles. There is also a small
town of the same name, situate 59° 50' lat. and 60 longit. on
the Kipper, in the government of Tambul, consisting of
400 timber-houses, and 804 male inhabitants, several of
whom are shop-keepers. It has two timber churches. The
merchants a few years since infcribed themselves in the
generals as possessing a capital of only 13,126 rubles. Here
is a considerable distillery.

BARITON, in Metes, a voice of low pitch, be-
tween a tenor and bafe. The term is formed of two Greek
words *γαύς, grave, and νοος, tongue.* But those who are not partial to
base voices, rather choose to derive the word from the
Italian verb *barite*, to bray.

BARK, in *Vegetable Anatomy*, is a term by which is
commonly understood the exterior part of vegetable bodies;
which is separable from the other parts of the plant without
much difficulty, during the season of vegetation; but at other
periods requires incision in water, or boiling, and when
detached by any of these means, the inner connection which
make it to the wood are necessarily destroyed.

When bark is thus separated, and subjected to micro-
sopic examination, it exhibits parts differing much in struc-
ture and use. These have been divided by authors into the
epidermis or cuticle, the cellular envelope or parenchyma,
and the cortical layers and fiber.

The Epidermis is situated most externally, and gives a cov-
ering to every part of the vegetable body, except the
authors and pits of flowers. Its texture is varied not only ac-
cording to the specife of plant to which it belongs, but allo by
the different parts of the same plant; thus, it is strong, dry,
and unyielding, upon the roots and trunks of trees; com-
monly smooth, glossy, and flexible upon leaves and flowers;
and sometimes it is villous, or covered with fine projecting
processes like hairs. The moll utal colour exhibited by the epidermis is
that of green upon the younger branches, and an ash-colour up-
on these parts of the plants which are most aged; it is how-
ever white and thinning in the birch, red and flowering in
the cherry-tree, and brown upon the horse-chestnut and apple-tree.

The epidermis is notwithstanding, in all cases, a trans-
parent membrane, and derives its colour from the substance
which is placed immediately behind it, in the same manner
as the colour of the skin of animals is produced by the exis-
tence of the mucous membrane.

In order to examine the epidermis of vegetables with suc-
cess, it is necessary to detach it from the cellular tissue, upon
which it is immediately applied. This is not difficult to per-
form, when the plant is full of sap, at which time the epider-
more must be removed by a fine knife or lancet; but at
other periods it must be submitted to a previous incision in
water before it will separate. When a portion of the vege-
table cuticle is thus obtained, it should be inspected under
water or spirits, and if viewed with a lens of moderate
power, it exhibits the appearance of a plexus or network,
by which the meshes are not vacant, but filled by a fine pell
ide membrane, as may be seen in Fig. 1. of Plate I. in *Ve-
etable Anatomy*; and the fibres composing the reticulation ap-
ppear more condensed in some places than others, as repres-
ented in the letters a a. Hill describes the cuticle of plants
as a triple membrane, or three plexuses laid one upon the
other. He observed, by employing high magnifying pow-
ers, that these plexuses were of regular forms; that what
appeared as fibres in the perpendicular directions were longi-
dudinal veils, and the spaces left between these veils were
oblong cells, close at their bottom, but open at the top; and
that the junctiop of the cells occasioned the appearance of
transverse lines; and thus the reticulation was rendered com-
plete. He even professed to have injected these veils, by pro-
ceeding an absorption of a solution of the cerula acetate,
or fugar of lead, and afterwards making it visible by adding
a mixture of lime and oat-meal; and in other instances he
filled the longitudinal veils by the absorption of the tre-
mip of cochineal. The description, which has been given
of the epidermis by Hill, does not appear, however, to de-
serve much attention, as it differs so much from that of
other writers. It is indeed true, that Du Hamel and others
have observed a second epidermis under the first, which ap-
ppeared more green, fresh, and succulent; and that on those
trees which frequently call the cuticle, as the birch, cherry-
tree, &c. there is a succession of layers; but this does not
prove that the epidermis is not a single membrane when first
formed, and that where there are more layers than one, each
is a perfect cuticle, proceeding in its turn to be exfoliated

4 L 2

or
or cut off. This mode of preparation resembles what takes place in animals, especially in some reptiles, which have the new cuticle perfectly formed, before the old one is parted with. Upon the trunks of most trees which are dicotyledons, the successive layers of epidermis continue to adhere together; each of these cracks, and gives way as the tissues in the fleshy part of the trunk permit, and hence the deep clefts which always appear in the bark of trees of any age. The several laminae, which are in this manner left surrounded by the cracks, are larger or have more extent, the nearer they approach to the wood, in consequence of the most external epidermis having first yielded to the growth of the tree.

No subject has occasioned greater controversy among vegetable anatomists, than the mode in which the cuticle of plants is formed. It was the opinion of Malpighi and Grew, that the epidermis was produced by the bulk vehicles of the cellular envelope, in consequence of their exposure to the air; but if the cuticle was formed by the dehydration of the cellular tissue, it would not admit of that extension which takes place in all circumstances to a certain degree, and which is so remarkable in the cuticle covering leaves, flowers, and fruits, and all parts of which the growth is rapid.

Several other circumstances might be mentioned to show that the epidermis can be produced by the drying of the cellular substance; thus when it is wounded or destroyed, and the part perfectly secluded from the action of the air, a new epidermis is soon produced without any exfoliation. The cuticle is in some instances formed, and in others continues to grow, under circumstances entirely beyond the agency of heat and evaporation, as may be observed in the fossil plant, and its appendages, and the internal surfaces of buds, &c.; but although the epidermis does not appear to be the cellular tissue simply dried by exposure, it is sufficiently plain that it is the continuation of the same membrane which forms the cellular envelope.

According to the latest observations made on this subject by Mirbel, who is one of the most ingenious vegetable anatomists of the present time, the lines which give the reticulated appearance to the epidermis, correspond in figure with the cells of the parenchyma, and are really the termination of the septa of these cells in the cuticle. (See fig. 2. Plate I. Vegetable Anatomy.) The tubular tissue, which in some cases is perceived upon the surfaces of plants, enters also into the composition of the epidermis, as represented in fig. 3. Plate I. Vegetable Anatomy. These small tubes are, however, upon close inspection, found to be composed of cells very much elongated, from whence it would appear, that the cellular substance is alone fitted for producing the epidermis of vegetables. The manner in which the cellular tissue is converted into cuticle, is probably beyond the reach of investigation; but that it is not the mere result of exposure to the air, is sufficiently plain from the facts already noticed. Like many other of the changes and operations of organic matter, we are unable to discover its immediate efficient cause, and in such cases, we must be content with observing the phenomenon, and stating it as the effect of a law of the system.

The growth of the cuticle is subject to considerable variety, according to the plant to which it may appertain, or the different parts of the same vegetable; thus, on leaves, flowers, fruits, &c., we do not meet with the successive layers of dead epidermis that exist upon trunks and branches. Some vegetables again have greater accumulations of dead cuticle than others; some get rid of these by repeated exfoliations; the plantane calls its cuticle every year; the epidermis of herbaceous plants and those which are not perennial, is always most delicate in its structure.

The epidermis presents no peculiarities in the monocotyledons, or those plants with one feimal leaf.

The uses of the external or cuticular portion of the bark have been much contended, although many of these are exceedingly obvious: it is evident that it serves as a defense to the whole surface of the vegetable; and accordingly we find its composition and strength dependent upon the functions which each part of the plant performs, and the injuries to which it is liable; on the roots it is tough and flexible; on the trunk rough, thick, and unyielding; on the leaves, flowers, and such parts as are only to perform temporary existence, and which at the same time exercise important functions, the cuticle is thin, delicate, and soft. The epidermis serves to guard the plant against the effects of meteors; it likewise affords to moderate the operation of heat and cold, and thereby contributes to the maintenance of the equality and independence of vegetable temperature; it regulates the action of light upon the cellular tissue, and thus co-operates in the fixation of that subtle matter; but the most important, perhaps, of all its uses is the giving pâlfage both to the fluids absorbed for the nutrition of the plant, and those expelled by transpiration, &c. Befides these known offices of the cuticle, others are ascribed to it. Many authors imagined that it restrained the growth of the whole tree; this however is disproved by the simple experiment of removing a portion of the cuticle, when it has been found that no bar or swelling took place; those trees also which are most distinguished for the cracks of the cuticle, are not observed to grow fatter than others. For a further account of the functions of the cuticle of vegetables, see Epidermis, Leaves, Etiolation, Transpiration, Inhalation, and Pores.

The cellular envelope. This was the name given by Du Hamel to the cellular substance immediately under the cuticle, in consequence of its extending over every part of the plant; by Grew it was called parenchyma; and Mirbel, whose abilities have been already mentioned, has with propriety made a distinction between the cellular tissue immediately next the cuticle, and that which is continued into the cortical layers; the first he terms the herbaceous tissue, the other the parenchyma.

The herbaceous tissue is composed of cells of an hexagonal figure; when applied to each other that each of the sides affords in forming the parieties of the adjoining cell, precisely like the construction of a honey-comb. The membranes composing these cells are extremely fine and transparent. See fig. 4. Plate I. of Vegetable Anatomy, in which the cellular structure is highly magnified, and also some foramin or pores, which establish a communication between the several apartments. These pores are not above the 500th part of a line in diameter. In some instances, the cells are elongated, especially in the parenchyma of the monocotyledons, which is exhibited in fig. 5. of Plate 1.; and it is remarkable, that in proportion as the vessels become elongated the pores of communication are more frequent and regular. In some cases, where the cells are very much elongated, they are arranged in rows succeeding each other by intervals, which are perfectly regular. (See Glands, and Pores.) The cellular tissue has been described, by some writers, as composed of a number of fibres, interwoven like the texture of felt. Hall says it only differs from the epidermis in having its parts more distinct; and Malpighi believed the cellular substance to be made up of distinct vehicles, collected together, which he called utricules, but, as we have already said, this is not the case; the whole being one continuous membrane, every part of which enters into the construction of two cells. Grew compared the cellular substance to the bubbles observed upon the surface of fermenting liquors, which is a very happy similitude, inasmuch as it conveys a very perfect idea of its appearance when only examined with a single
less; but when the highest magnifying powers are employed, the hexagonal figure of the cells becomes evident. The herbaceous tisue is the immediate cause of the colour of the epidermis, and its own colour, again, depends upon that of the fluid contained in the cells, which is usually green, but is sometimes brown, red, yellow, &c. This juice is of a renewable nature, which circumstance would appear, as well as the colour, to be the effect of its continual exposure to the light. It is probable that the sap is originally deposited in the cells, in the state in which it is absorbed, that is, consisting of water and carbonic acid gas, and that there, by the agency of light, it undergoes a decomposition; the oxygen contained in both the water and fixed air being discharged by the pores of the cuticle, the carbon of the carbonic acid, and the hydrogea of the water producing the oils and the resins. A number of consequences arise from this operation, not only to plants themselves, but to the animal world, which make it the most important process carried on in the vegetable system. See Etiolation, Light, Oxygen, and Transpiration.

Parenchyma. This part is composed of cells like those described in the herbaceous tissue; indeed, the only difference which exists between these two parts of the cellular substance, is in the colour of the contained fluid; the one being usually green, in consequence of its exposure to the light; whilst the other, not being situated so superficially, is generally found transparent. In other respects, they agree in structure, and appear to be formed of the continuation of the same membrane.

The parenchyma of Mirbel corresponds with the tissue cellulare of Du Hamel, the utricles of Malpighi, and the parenchymatous substance of Grew; whilst the herbaceous tissue is more fitly the envelope cellulare of Du Hamel.

The parenchyma is not confined to the superficialities of vegetables; it passes between the fibres of the cortical and ligneous layers, and forms the pith or medulla; the phellogen of leaves and petal is dependent upon its existence; fruits, seeds, and the embrio plant, are almost entirely composed of it; bulbous, and other succulent roots, owe their bulk to it; nor other structure is observable in the fungi and fungi; in short, the cellular tissue is the first and final state of vegetable organization, and serves as the connecting medium between all the parts of the plant.

There is, strictly speaking, no circulation of the juices contained in the cellular tissue; fluids, however, being admitted into any of the cells, easily pass into the neighbouring ones, by means of the small pores of communication, already described.

The texture of the cellular substance is very speedily broken down by maceration, or boiling in water; which circumstance should be recollected in preparing the parts of plants for examination; otherwise the natural connections, which are produced by the cellular tissue, may escape observation.

The Cortical Layers and Liber. When the epidermis and the cellular envelope have been removed, the remainder of the bark appears to be made up of a number of reticulated fibres, containing cellular substance in their interstices; this appearance of the cortical fibres is plain to the naked eye, especially if the cellular tissue, which passes amongst them, be at all destroyed by maceration, or other means; but if examined by the microscope, these fibres become very distinct; their arrangement is then perceived to be singular, and difficult to describe. The fibres in their course, although longitudinal with respect to the plant, are not parallel with each other; each makes a flight curve, and thus comes into contact with the one adjoining, with which it usually becomes incorporated or united, and thus produces a plexus or network, which was called by Du Hamel the cortical plexus; sometimes these fibres merely touch each other, and then go off again, to compose another mesh in the plexus, see fig. 6.

Plate 1. of Vegetable Anatomy; and point out the reticulation produced by the fibres, and add the meshes, or spaces left between them. The meshes are not vacant in the recent vegetable, but filled with cellular tissue, which admits of the transverse motion of the fluids in plants. Du Hamel shows, that upon examining these fibres by a high magnifying power, each appeared to be a faciulus, the fibres of which could be again resolved into fibres, and these again could be divided into others, until they became too minute for observation; he, however, as well as other authors upon the subject, supposed that the cortical fibres to be vessel. See Vessels.

The cortical layers, as the term implies, are not single, but consist of a number of concentric laminae, placed upon each other in such a manner that the meshes of one plexus are situated opposite to those of another. Fig. 7, Plate 1, exhibits this circumstance as it has been represented by Du Hamel. The cellular tissue passes through all these meshes, and thus produces a kind of intertexture, which Malpighi compared to cloth, and which the longitudinal fibres of the wood, and the transverse fibres of the vessel are called the tesselary or vessel layers. These vessel layers are smaller, the more internally they are situated; the gradation in this respect is regular from the external layer to the wood, as may be perceived in fig. 8, 9, 10, in Plate 1, of Vegetable Anatomy. In the moss internal plexus, fig. 10, the longitudinal saccidia are nearly parallel, and so close to each other that the interstices are almost obliterated.

The cortical layers, or network, are found to increase in number according to the age of the part which furnishes them. Thus Du Hamel reckoned only five or six plexuses upon the upper branch of the hinde tree, and seventeen at the base of the trunk of the same tree.

The same disposition of fibres does not exist in all plants; in the lattage, or the lace bark tree, for instance, the cortical plexus exhibits a texture like gauze or lace. See fig. 11.

Plate 1. of Vegetable Anatomy.

Much confusion may be observed in the descriptions which authors have given of this part of the bark called liber. The name would appear to have taken its origin from the likenesses which the cortical plexuses, when partially separated, bear to the leaves of a book; and, conformably to this idea, Grew and others have considered all the cortical layers as belonging to the liber; whilst, on the other hand, Malpighi has given this name to the innermost layer only. The liber is, however, generally allowed to be the most important part of the bark, and is that substance for which the cortical layers are formed. When the bark is stripped off a tree in a state of full vegetation, in a very short time a gelatinous substance is observed to exude upon the surface of the wood; this substance acquires organization, and is converted into a new bark. It was termed pavisum by Du Hamel; the manner in which it is produced, and its composition, are both unknown, but its high utility in the vegetable economy is proved by some beautiful experiments. This formative or organizing substance is constantly renewed during the period of vegetation, and immediately produces the liber, which is intestibly converted into the layers of bark, and the alburnum, or white imperfect wood, which is next the bark; and hence the acceions of bulk in perennials, which are made every year, and indicate the age of the tree. That the liber is the immediate source of both the wood and the bark, or the central point or fountain of organization, is proved by two very elegant experiments made by Du Hamel. He separated a portion of the bark of a plum-tree, and made sure that it possessed the inner cortical layers.
layers or liber; he then removed the similar portion of bark from a peach-tree, and replaced it with the piece taken from the plum-tree. The graft perfectly succeeded; and upon a future examination he found, that not only the engraved bark continued to grow, but that a corresponding portion of wood was produced, which was very distinguishable from the rest of the tree, as it polished the red colour of the wood of the plum-tree, from which the bark had been removed. The other experiment is equally decisive; he pitted several silver wires through the bark of a tree, in the formation of full vegetation, some of the wires only went through the parenchyma, whilst others were inserted into the liber; those which had only penetrated the cellular tissue, obeyed the eccentric propensities of the bark, and as the tree grew came nearer the surface; but the wires which had passed through the liber, were carried towards the centre, and after some years, were found covered with many layers of wood.

The conclusion which Du Hamel drew from these experiments was, that the bark produced the liber, the alburnum, and the wood; but it is Mihel's opinion, that the wood in giving origin to the cambium, produces the liber, which is finally converted into both the bark and wood. For the further discussion of this subject, see Cambium, Liber, and Wood.

It should be observed, that the period of vegetable existence depends upon the power of the plant to produce the cambium, and consequently, the liber; accordingly, in herbs, most of which do not live more than two years, the succulent layers which characterize the wood of trees, are not to be seen.

Hitherto we have been describing the arrangement of the cortical layers, in the dicotyledons; in those plants, however, which are called monocotyledons, or having one seminal leaf, the disposition of these parts is very different; only the cuticle and cellular substance are found on the surface of these vegetables; there are no concentric layers of either bark or wood; the interior of the plant is filled with parenchyma, in which are contained the woody fibres, scattered at irregular distances; the cambium is deposited round each fibre, and there produces the tubular and cellular tissue; the tubular tissue forms the porous wood or alburnum, which contracts in thickness, elongates and is infinitely converted into the perfect wood, and in contracting is detached from the parenchyma and leaves a vacancy which is presently filled up by a new cambium; each of these fibres, therefore, might with propriety be considered as a distinct vegetable, inasmuch as it has the means of an independent growth. See Cambium, Wood, Monocotyledon, and Dicotyledon.

It has already been observed, that some of the more simply organized vegetables, such as the fungi and fuci, do not possess in any of their substance either cortical or woody fibres, but are altogether composed of the cellular tissue.

After the account which we have given of the different parts entering into the structure of the bark, it is unnecessary to insist upon its uses in the vegetable system; in it reside almost all the powers and energies of the plant; wounds only are healed by it; upon the exact contact of the liber of two trees depends the whole of the fucres in engraving; and in the bark are prepared not only all the juices and febrifications which are required for the formation and increase of the plant, but those peculiar substances which are applicable to so many of the purposes of common life and of medicine. See Versilia, Sucra Propria, and Secretion.

Bark, Peruvian, Cortex Peruana. The high importance in medicine of the Peruvian bark has appropriated to it exclusively the term of the bark. We shall describe it under the botanical and now official name of Cinchona.

Bark, in Agriculture, a substance frequently employed by cultivators as a manure to particular kinds of land.

The bark of trees in general, and particularly that of the oak, becomes an useful manure after it has been employed by the tanner in the preparation of leather. One load of oak bark laid in a heap and rotted after having been thus used, it is said, will do more service to stiff cold land, and its effects will last longer, than two loads of the richest dung. Mr. Miller in his Dictionary observes, that it is much better for cold strong land than for light hot ground, if it be used alone as taken from the tan-yard; because it is of a warm nature, and it will loosen and separate the earth so effectively, that, by only employing it two or three times, a strong soil, not easy to be wrought, may be rendered perfectly light and loose; but by mixing it with earth of a nature contrary to that which it is intended to correct, and in a proportion fitted to the nature of the foil on which it is to be laid, it will prove a good manure for almost any sort of land.

And Mortimer has even asserted that it will alter and change the very nature of the soil, and turn it into a rich black mould. As it abounds with vegetable matter derived from the tree to which it belonged, and is strongly impregnated with animal materials by the length of time which it has remained in the tan vats, in contact with the skins and hides of animals, it must necessarily prove beneficial as a manure where judiciously applied.

When laid on grass-land it has been recommended to be spread out over it soon after Michaelmas, that the winter rains may wash it into the ground to the roots of the grasses, as when laid on in the spring, it is apt to burn the grases, and, instead of improving it, do considerable injury for that reason. But when employed on arable land it should be applied and spread before the last ploughing, in order that it may be turned down lightly into the soil so as the fibres of the corn may easily reach it in the spring; when it lies too near the surface, it has however been supposed to forward the growth of the crop at too early a period, and to be nearly consumed in the spring, when the nourishment is chiefly wanted for its support.

In his work on gardening and agriculture, Mr. Bradley says, he advised a gentleman to whom a considerate quantity of bark was left, upon the expiration of the lease of a tan yard, to lay some of it upon a piece of stubborn four land; which he did with much success, that his product was admired by all the gardeners and farmers in the neighbourhood: For such soils, he thinks, it should be mixed with a sandy mould or earth; and that one-third of bark to two-thirds of such materials will be a sufficient proportion for clays in general, laying on about one hundred and fifty cart loads upon the acre.

Worldly remarks, that the barks or rinds of other trees, though not of so high a value as that of the oak, which is the first principally used by tanners, most of necessity enrich either corn or pasture grounds, if broken into small pieces, and laid upon them.

It has been found from experience, that by mixing caustic line with tanner's bark, in the proportion of about two parts of the latter to one of the former, the conversion of the bark into vegetable mould may be greatly promoted, and that the composition when employed as a top dressing for either turnips or grases proves an excellent manure, promoting the growth of the crops in a rapid manner.

Bark, in Gardening, comprehends the exterior parts or coverings of trees, plants, and vegetables, and also such substances in their dead state after being separated from them, and employed for different purposes.

The bark of trees, &c. is in itself a hard porous texture, and adheres loosely to the liber, or inner bark. It is
fulation, and the interior bark, which is dry and porous, is used for making paper, and the outer bark, which is fibrous, is used for making baskets and other articles of utilitarian value.

The interior of the trunk of a tree, like the alburnum or roots described above, contains thin, much mucilaginous or nutritious matter; as the bark of elm (ulmus), and of holly (ilex), and of all other trees or shrubs which are armed with thorns or prickles, which are designed to prevent the depredations of animals on them, as the hawthorn, gooseberry, and gorse, eridania, ericas, graffularia, iles. The internal bark of these vegetables may, he thinks, be constipated to their albumen, which is inverted and probably all used as food for ourselves or other animals in years of scarcity, or for the purpose of fermentation; as he doubts not but the inner bark of elms, detached in the spring by being boiled in water, might be converted by the addition of yeast into small beer, as well as the alburnum of the maple and birch (acer and betula), all of which are now suffered to be eaten by insects, when these trees are felled. For the fugar, which is extracted from the vernal sap-juice of the maple and birch, as well as that found in the manna ash (fraxinus urna), teems, he observes, to reed during the winter months in the root or alburnum, rather than in the bark properly so called, and to become liquefied by the warmth of the spring, or diffused by the moisture absorbed from the earth and conveyed to the opening buds; but reeds solely in the roots of perennial herbaceous plants; and in the economy of grasses, and he supposes, of the fugar-cane, it is deposited at the bottom of each joint, which is properly at the root of the stem above it.

Of the above plants, continues he, the bark of the holly not only yields a nutritious mucilage, and thus supplies much provender to the deer and cattle in Neddwood forest, by the branches cut off and thrown upon the ground in severe feasons of fruit and snow, but contains a rensic material, which is obtained by boiling the bark and washing away the other parts of it. This rensic material pothishes a great adhesiveness to feathers and other dry porous bodies, and has hence obtained the name of birdlime, and much resembles the caseum bozor or clastic resin brought from South America, and also a fossil clastic bitumen found near Rutreek in Derbyshire, both in its elasticity and inflammability. Hollies may, he therefore supposes, be worth cultivating for this material besides the uses of their wood; as the doctor was informed, that thirty years ago a person who purchased a wood in Yorkshire, sold to a Dutch merchant the bird-lime, prepared from the bark of the numerous hollies, for nearly the whole sum given for the wood; which, if it could be harden'd, might probably, he says, be sold for the clastic resin above mentioned. Whether this resembles the nutritive rensic matter obtained in wheat flour, when the mucilage and starch are washed from it, might, he thinks, be also worth inquiry.

Other barks contain bitter, redcinous, aromatic, or acid materials, which supply the leeps of medicine, as Peruvian bark, cascarilla, cinnamon, and were designed by nature, he supposes, to protect those vegetables from the depredations of quadrupeds or insects. Hence, says he, many trees, and even the wood of them, after it is dried and made into domestic furniture, is never devoured by worms, as the mahogany, cedar, cypress, and hence many plants, as the foxglove (digitale), hounds-tongue (cyngophylla), hem-bane (hygromia), and many trees and shrubs by any animals, as their juices would be poisonous to them, or if they ingested with their stomac, if their distinguting flavours to the nose or palate did not prevent their eating them. The same defence of the vegetable kingdom from human digestion, except those which have, in long procees of time, beenilded and cultivated, appears, he remarks, from the relation of some unfortunate shipwrecked travellers, who have passed hundreds of miles along uninhabited countries without finding an excellent vegetable production.

Other barks contain refringent or colouring particles, employed in the arts of dyeing and tanning, as that of the barberry, oak, and ash (fraxina, quercus, fraxinus.) The art of tanning consists in filling the pores of the animal mucous membrane with these refringent particles found in some vegetables, which are believed to possess a quality of shortening the fibres of the animal bodies, and thus the gall produced on its leaves by the punctures of insects, the hair is said to be shortened. Whether this proceeds be occasioned by the chemical coagulation of the mucus, of which these fibres totally or in part consist, or by capillary attraction tending to distend these fibres in breadth, and thus to shorten them, as a twisted string is shortened by moiture, has, he says, not yet been well investigated. By thus impregnating the pores of animal skins with vegetable particles they become lees fable to putrefaction, as confining of a mixture of animal and vegetable matter, as well as much better adapted to many domestic or mechanical purposes.

The art of dyeing consists likewise in impregnating the pores of dry substances with a solution of the colouring matter extracted from vegetables by the capillary attraction of these pores to the coloured solution; and, secondly, by a chemical change of these colouring particles after they have been imbibed, and the water of the solution exhaled, by again steeping them in another solution, which may chemically affect the former. Thus, says he, as green confids of a mixture of blue and yellow, it may be best produced by boiling the material designed to be dyed, first in a decoction of one of these colours, as of indigo, and then in that of another, as of the bark of barberry. And as a solution of iron becomes black, when mixed with a decoction of oak-galls, by being in part precipitated; it is probable that the particles of this combination, of a solution of iron with refringent matter, may be larger than either of these particles separately; and, therefore, that if a dry porous substance be imbued, first in a decoction of oak-galls, and, after being suffered to dry, is then immersed in a solution of iron, the black tinge will penetrate into minutest pores, and thus become more intense than if the substance had been immersed in the black dye already prepared.

Other barks are, he adds, used for apparel, paper, cordage, and for many mechanical purposes, owing to the strength and tenacity of their fibres, or to the flacces of them; as hemp (cannabis), flax (linum), for the purpoes of spinning and weaving. The bark or leaves of the papyrus, a flag of the Nile, was, he says, first used for paper; and the bark of the mulberry tree is still made into cloth at Othaike, and other southern islands.

The art of separating the fibres of the bark of plants, as they confit of the caudexes of barks, or the connecting veivals between the plumules and the radicles of them, is, he observes,
Bar

Observes, performed by soaking them some weeks in agitant water, till the mucous membranes, which connect these fibres, are destroyed by putrefaction; and afterwards by drying them, and beating off with hammers what may still adhere.

These fibrous parts of the bark of trees, as they contain no fuchinal matter, like the alburnum, are, he observes, much less liable to decay than the lap-wood, or perhaps than any part of the timber. Maupertuis, he adds, who went to Lapland to measure a degree of the meridian, says, that among the numerous trees which lay upon the ground, destroyed by age, or blown down by the winds, many birch trees appeared whole, owing to the undecayed state of their bark, but crumbled into powder on being trod upon; and that the Swedes took the practice from this of covering their houfes with this unperishable bark, on which they sometimes lay firl, and thus polifhes aerial gardens.

To increase the quantity of bark, it muft, the doctor remarks, he remembered, that the leaf-buds, or viviparous offpring of trees, as they form new buds, acquire new caudexes extending down into the ground; and thus increase the bark of the tree in thickness; but the flower-buds acquire no new caudexes, but die as soon as they have ripened their feed, and consequently do not increase the thickness of the bark. Whereas one method of increasing the quantity of the bark is to increase the number of vigour of the leaf-buds, in contradiction to the flower-buds, which may be done by pinching off the flowers as soon as they appear; and as the bark becomes gradually changed into wood, this may be one method, also, he thinks, of forwarding the growth of timber trees.

It is added, that the method of preferring the bark of trees from moss caps in rubbing off that parasite vegetable in wet weather, by means of a hardifh brush; which is said to be used with advantage on the apple-trees in the counties; and may, at the same time, give motion to the vegetable circulation, or forward the afcent of their juices aborbed by the radical or cortical absorbtions. In dry weather, the brush should be frequently dipped in water. Washing the barks of wall trees by a water-engine, may also facilitate the protrusion of their buds in dry-leaves; and might probably prevent the canker, if applied to dwarfs or elder apple-trees. Other parasite vegetables must be occasionally destroyed where they occur; as the lichens, fungi, miltedote, with the ivy and other climbers, as some kinds of lonicera, elmatis, and familas, woodbine, virginus-bower, and fumitory.

It is further remarked, that when a wound is made in the bark of a tree, so as to expose the alburnum to the air, the upper lip of the wound is liable to grow fatter downwards than the lower one is to grow upwards, owing to the former being supplied directly with nutritive juices secreted from the vegetable blood after its ventilation, and consequent oxygenation in the leaves; whereas the lower lip only receives these juices laterally by the infeoration of vessels. Over these wounds the cuticle is liable to project, and to supply a convenient hiding-place for insects, which either eat the new fibres of the growing bark, and perforate the alburnum; or by their moisture, their warmth, and their excrements, contribute to the decay of the alburnum, and prevent the healing of the wound. These dead edges of the projecting bark or cuticle should therefore, it is said, be nicely cut off, but not so as to wound the living bark.

It is remarked, that platters of lime or of far with full-limate of mercury, have been recommended to preserve the wounded parts from the air, and from moisture, and from insects; but as all these materials are injurious to the fibres of the living bark, they should be used with caution, so as not to touch the edges of the wound, but only to cover the alburnum; for this purpose, white lead and boiled oil, mixed into a thick point, or with the addition of sublimate of mercury; or of arfines, or of spirit of turpentine, may probably answer the purpose; and may be of real utility on the wounds of these trees whose wood contains lefs acrimony, and is therefore more liable to be bored into and eaten by a large worm or maggot, almost as thick as a goife-quill, which the doctor has seen happen to a pear-tree, so as to consume the whole internal wood, till the tree was blown down.

In respect to the caution necessary to be observed in not touching the living edges of the wounded bark with such materials as may injure the tree by their absorption, he remembers seeing several young elm-trees which died by their holes having been covered, as he was informed, by quick-lime, mixed with cow-dung, to prevent their being injured by horses; and he has seen branches of peach and neftarine trees destroyed by sprinkling them, when in leaf, with a light solution of arfenic, and others with spirit of turpentine.

The composition recommended by Mr. Forfyth, in his "Treatife on the Culture and Management of Fruit Trees," which is constituted of cow-dung, effente line, wood-ashes, and river sand, seems however to have been made use of in those cases with much advantage, and without any inconvience having been experienced in this way.

It is further stated, by the author of Phytologia, that a more curious method of cure is said to have succeed, where the bark of a tree has recently been torn off, even to great extent; and this is, by binding the fame piece of bark on again, or another piece from the same tree, or from one of a similar nature, nicely adapting the edges of the bark to be applied to the edges of that which surrounds the wound of the tree, which, it is said, will coalesce, in the fame manner as the veifils of the bark of an ingrafted fein, unite with those of the bark of the fock ingrained on; which is ftrongly analogous to the union of inflamed or wounded parts of animal bodies, as in the cure of the bare-lip, or the infiltration of the living tooth from one perfon into the jaw of another.

If the bark, over the cankered parts of apple-trees, adds the doctor, could be thus renewed by paring the edges of the mortified bark to the quick, and then nicely applying a piece of healthy bark, from an apple-tree of inferior value, and securing it with an elfaic bandage, as a fhed of fanuel, it would be a very valuable discovery. Another method, where a branch of a valuable tree is in the progress of being destroyed by canker, might, he observes, by inclosing the cankered part, and some inches above it, in a garden pot of earth previously divided, and supported by flakes, and tied together round the branch, which might then strike roots in the earth of the garden-pot; and, after some months, be cut off, and planted on the ground, and might thus be preferred, and produce a new tree; which experiment (the doctor says) he has tried on two apple-trees, and believes it will succeed.

Bark, in its dead state, after having been employed in the vat of the tanner, is found to be a material of great utility for the purpose of confituting thofe hot-beds in stoves and pits constructed for them, that are usually denominated bark-beds, and which from their being much more regular and durable in the temperature of their heat, than thofe formed from dung, become a great deal more convenient and useful for different purposes of the gardener; and are of course employed with much advantage in the growth and culture of various tender and curious exotic
BAR

exotics that require the aid of an uniform degree of artificial heat in this climate. See Bark-Bed, and Bark-Pit.

Barks of Trees. (Chemical Analysis of). Since the time that chemists have introduced a considerable degree of unaided and comparative accuracy in the analysis of vegetable matter, many of the general classifications of medical chemistry have been found inconvenient and liable to error. This is particularly the case when vegetable substances, designed for chemical examination, are called anatomically, or according to the ufs which they fulfill in the economy of the plant, rather than the properties which they exhibit under the hands of the chemist. Thus, in the infancy of the barks of trees, scarcely any common chemical character can be alligned to them, as their composition varies in almost every order of plants, and as they partake largely of the qualities of the common juice which circulates in the vegetable. If there is any principle common to all barks, it is (besides water, an invariable ingredient in vegetable matter), the ligneous fibre or inflexible woody part, but even in this respect some very important differences occur in the several species which cannot be neglected by the chemist. The substances which render many barks peculiarly interesting in the arts and in medicine are, TANNIN, or the principle which causes several of them to be employed in the art of tanning; EXTRACT, a substance varying considerably in properties, and much used in medicine; and the GALLIC ACID, the basis of many of the black dyes and pigments when in conjunction with iron. These principles, however, are not peculiar to barks, but they are all found in other parts of vegetables. We have an example of an excellent analysis of the bark of the Citron, by M. Fourcroy, to which article we shall refer the reader who may wish to have a good specimen of the chemical analysis of vegetables.

Barks, general observations relating to. From the experiments of M. Buffon, it appears, that trees stripped of their bark through the whole length of their limbs, die in about three or four years. But it is remarkably, that trees stripped in the time of the sap, and suffered to die, afford timber heavier, more uniformly dense, stronger, and fitter for service, than if the tree had been cut down in its healthy state. Something of a like nature has been observed by Vitruvius and Evelyn. Mem. Acad. Scien. 1738.

As animals are furnished with a panacitic adipofis, usually replete with fat, which invades and covers all the fleshy parts, and freezes them from external colds, plants are encompassed with a bark replete with fatty juices, by means where the cold is kept out, and, in winter-time, the epicile of ice prevented from fixing and freezing the juices in the velifes: whence it is, that some fort of trees remain ever green the year round, because their barks contain more oil than can be spent and exhausted by the sun, &c. Ray's Wild. of God, &c. part i. p. 103.

The bark has peculiar difficulties, and is infected with insects peculiar to it. Wounds of the bark often prove mortal. See Cancer.

There are many great kinds of barks in use in the several arts: home in medicine, as the quinquina, or jujufis bark, mace, chacarilla, &c. others in dyeing, as the bark of the elder; others in spicery, as cinamon, cafia lignea, &c. the bark of oak in tanning; others on other occasions, as that of cork; that of a kind of birch is used by the Indians for canoes capable of holding twenty-four persons.

Of the bark of willows and linden trees is ordinarily made a kind of ropes. The Siamese make their cordage of the bark of the cocoa tree, which is also the cafe in moft of the African and African nations. In reality, flax and hemp, with all their toughnefs, are only the sap-veilils, or ligneous fibres of the bark of those plants.

The ancients wrote their books on barks, especially those of the ash, and fift or lime-tree; not on the exterior or outer barks, but on the inner and finer, called phyllary, which are of fo durable a texture, that there are manufcripts on them, still extant, a thousand years old.

In the East Indies they manufacture the barks of a certain tree into a kind of stuff or cloth. It is fpun and dreft much after the manner of hemp. The long filaments separated from it, upon beating and steeping it in water, compose a thread, of a middle kind between filk and common thread; neither so soft nor bright as filk, nor so hard or flat as hemp. See Neumans Works, p. 428. Note. Some of these fluids are put barks, and are called pinacles, biam-bornes, &c. In others they mix filk with the bark, and call them gingham and cillas: the founflanges too are put fift, put bark, and are only distinguished by being flriped. The Japanife make their paper of a fpecies of mulberry tree. (See Mort. s.) In the island of Oudeiba, the natives make their cloth, which is of three different sorts, from three different kinds of bark; that of the mulberry tree, that of the bread-fruit tree, and that of the cocoa tree. That made of the mulberry is the fickest and whitest, and worn chiefly by the principal people. It is manufactured in the following manner. When the trees are of a proper fize, they are drawn up and flriped of their branches; after which, the roots and tops are cut off; the bark of these rods being then flit up longitudinally is easily drawn off; and when a proper quantity has been procured, it is deposited in some running water to soak, and kept down by heavy fones: when it is fuppoled to be sufficiently focked, the women go down to the brook, and, flipping themselves, fit down in the water to separate the inner bark from the green part on the out-side; for this purpose, they place the under fide upon a flat smooth board, and with a kind of fhefl scrape it very carefully. dipping it continually in the water, till nothing remains but the fine fibres of the inner coat. Being thus prepared in the afternoon, they are fpread out upon plantain leaves in the evening, and placed in lengths of about eleven or twelve yards, one by the fide of another, till they are about a foot abroad, and two or three layers are also laid one upon the other; care is taken that the cloth fhall be in all parts of an equal thicknes, fo that if the bark happens to be thinner in a particular part of one layer than the reft, a piece that is somewhat thicker is selected to be laid over in the next. In this flate it remains till the morning, when a great part of the water which it contained, when it was laid out, is either drained off or evaporated, and the several fibres adhere together, fo that the whole may be raised from the ground in one piece. It is then takenc away and laid upon the smooth fide of a long piece of wood, prepared for the purpofe, and beaten by the mallet. The instrument used for this purpofe is a fquare wooden club, having each of its four fides or faces marked, lengthwise, with small grooves or furrows of different degrees of fineness; these on one fide being of a width and depth sufficient to receive a small packthread, and the others finer in a regular gradation, fo that the lat is not more than equal to sewing filk. They beat it with the coaflest fide of this mallet, keeping time like our smiths; it fpreads fift under the strokes, chiefly, however, in the breadth, and the grooves in the mallet mark it with the appearance of threads; it is Successively beaten with the other fides, and left all with the fift, and it is then fit for use. Of this cloth there are feveral forts, of different degrees of finenes, in proportion as it is more or fefs beaten; and the other cloth
also differs in proportion as it is beaten, and the several cloths differ also from one another in consequence of the different materials of which they are made. The bark of the bread-fruit is not taken till the trees are consider-ably longer and thicker than those of the mulberry; the proceeds afterwards is the fame. Of the bark of a tree which they call "poerou," the "hibiscus tiliaceus" of Linnaeus, they manufacture excellent matting; both a coarse fort on which they sleep, and a finer which they wear in wet weather. Of the fame bark they also make ropes and lines, from the thickness of an inch to the size of a small packthread.

**Bark, Indian, Thuriia coccine, a medical bark, brought from the East, rolled up like cinnamon, of a rusty colour, a warm aromatic, bitter taffe, and pleafant smell; fometimes used in fumigation againft fits of the mother.**

**Bark-Mills.** See Mill.

**Bark, grafting in.** See Engrafting.

**Bark, in Navigation,** denotes a little veffel for the sea, usually with pointed or triangular fails, in number two or three at the moft. The term is ufually apprpfiated by fpeakers to thofe small ships which carry three mafts without a mizen top-fail. Our northern mariners in the coal-trade, apply the term to a broad-ferned ship, which carries no ornamental figure on the ftern or prow. Bark is also a Mediterranean veffel, with three mafts and no bowsprit; the foremost rakes much forward and carries a lattice fall; the main-mast is a pole-mast, and carries three square fails, like the polaire; the mizen-mast is fmall and carries a mizen and a top-fail. Fihing-barks are small veffels with one maff, ufed for fhiping, &c. by the Spaniards: on the maff they carry a square main-fall, with a jib upon the bowsprit. Japanese barks are veffels similar to junks, 80 or 90 feet long on one deck, which have only one maff, that carries a square-fall, and forward one or two jibs made of cotton. They only use fails, when the wind is large. Barks of Cracala and Irafts of Sunda are veffels with flush-decks, high fhare, and sharp forward. They have one maff, and the fail is similar to the Caracores, being long and narrow. Thofe veffels are kept from ufing by a fort of beams croffing the veffel and bending downwards at the ends which fallen to a long round or flat piece of timber. Bombay-barks are called Dinga. See Plates of Ships.

The word Bark is derived by fome from the Latin barca; by Fournier, from Barces, a city in Africa; and by Tolentus, from Barcelona.

Some authors use the word bark for any veffel that has no masts.

**Bark, Armed, a kind of fire-veffel filled with foldiers, ufed both for making falls, and to attack galleries, and bar the paffage over them.**

**Bark, Long, is a small veffel without deck, longer and lower than the common barks, being sharp before, and commonly going both with fails and ears. It is built after the manner of a floop, and in many places is called a double floop.**

**Barks, Water, are little veffels ufed in Holland for the carriage of fresh-water to places where it is wanting, as well as for the fetching sea-water to make salt of. They have a deck, and are filled with water up to the deck.**

**Bark-Bed, in Gardening,** that fort of hot-bed which is either wholly or principally constituted of tanner's bark. This fort of bed, from its preferring the moist uniform and regular degrees of heat, is found by much the moft ufeful in the propagation and culture of all kinds of tender exotic plants that are brought from warm climates, and which stand in need of the continued affifiance of artificial heat in this part of the world. Beds of this nature, with a little trouble in the management of them, are found sometimes to support a pretty uniform and regular temperature for a consider-able length of time.

There are the kind of hot-beds that are generally employed in hot-houses, being formed in pits or cavities constructed for the purpose in them, frequently the whole length of the houses, six or seven feet in width, and three in depth, being inclosed by means of brick-work. See Bark-Pit.

In these beds, the pots of fuch tender exotics as have been mentioned, are plunged and supported; and they at the fame time afford affifiance in supplying fresh houses or fieves with thofe degrees of heat that may be proper for the growth and support of various other plants that do not require to be plunged into the beds, the heat of the surrounding air, produced in this way, being sufficient for their growth and prefervation. Thus, by the aid of bark-heat, and that of fire during the feverity of the winter feafon, the gardener is enabled to imitate, within the hot-houfe, the temperature of diftant climates, and not only to cultivate and bring to perfection the *Brouelia Ananas,* or pine-apple, but also various other tender plants from different quarters of the globe, both of the herbaceous and woody kinds, and to exhibit them in their moft healthy and beautiful fates in this country.

Bark hot-beds are likewife occasionally formed in pits constructed for them, in the open ground, separately and detached from the hot-houfe. These are wall'd round with bricks chiefly above the furface of the ground, having a frame or coping of wood upon the top on which glafs lights are fixed so as to slide with facility. See Bark-Pit.

In thefe pits the bark-beds are made to the depth of three feet or more, in order to afford an uniform and faving heat, for the purpose of raiuing and propagating different sorts of tender plants from seeds, cuttings, &c. both of the fove and green-house kinds, as well as thofe of the natural ground. Such beds are of course of great utility where there are large collections of tender exotic plants, and as nurfery-pits for young pine-apple plants to supply the fove or pinery annually. See Stone.

Beds formed of bark are alfo employed with fuccefs in raiuing various sorts of early productions of other kinds, as early strawberries, melons, peaches, French beans, &c. which by the regular and moderate heat which they afford are moftly brought forward in the greateft perfection. They are likewife made ufe of in forcing different sorts of curious flowers, both of the bulbous, tuberefe, and fibrous rooted kinds, into early bloon; as hyacinths, dwarf tulips, narcissus, jonquils, amanemas, ranunculufes, pinks, &c. also many flowering plants of the small shrubby kind, as rofles, hypericums, &c.

Bark-beds are alfo employed with great advantage in forcing frames for the purpose of producing early fruit of the apricot, peach and grape kinds. See Forcing Frames, and Hot-Walls.

Hot-beds constituted of bark, from the flow and regular manner in which the heat is in common evolved, are not liable, as thofe of dung, to injure the plants by their fream; they are therefore to be preferred for all the more important purposes of forcing where the material can be obtained.

The heat of them may be perpetuated for a great length of time, by having recourse occasionally to the practice of forking or turning them over, adding in fuch operations about a third part of new tan or bark. The beds are how-
ever to be wholly, or in a great part, renovated every autumn or spring.

There are different sorts or sizes of bark made use of for the construction of these beds, as coarse, middling, and small. The first kind is the longest in taking on heat, and is apt to heat the air more in the beginning. The latter, as it is of the longer duration. The second sort heats sooner, is more regular, and pretty durable in its effects. But the last kind heats the quickest, yet is the weakest, and soonest becomes earthy, consequently the least proper for the purpose. Where there is a choice of the matter, the middle sort, or a mixture of it and the coarse, should constantly be preferred, admitting as little of the small as possible; and care should be taken that it be perfectly fresh from the vat of the tanner. When the bark is wet after being brought home, it is a good practice to throw it up into heaps or ridges for a few days, in order that it may be drained and rendered more dry, as without such precaution the process of fermentation may be too much retarded.

The periods of making beds of this nature must be regulated by circumstances; but where they are intended for pine-apple plants, they should be prepared about the latter end of September or beginning of October, in order that they may afford a good heat during the winter season: but when the raising of plants from seeds, cuttings, &c. or the forcing of culinary vegetables, and fruits or flowers, are the principal objects, the spring may be the most suitable time, as in January or March. For particular uses they may, however, be made at any period.

In forming the beds, the tan or bark, prepared as above, is thrown into the pits that are constructed for it; and where there is old, the new bark well mixed and blended with it, by means of the tan-fork, quite to the bottom; then it is the practice to begin at one end and carry them on to the full breadth and depth, without treading upon them, as that would render the bark too solid for the process of fermentation. It is necessary to remove the surfaces of the beds about three or four inches higher than the tops or copings of the beds or pits, in order to allow for the settling that may take place. In the making of this sort of hot-beds for the purpose of raising pine-apples, the author of the "Scotch Forcing Gardens," in order to avoid the danger of too much bottom heat, never admits of the tan being filled, or of more than one eighth part of new tan being added, which is introduced by skimming off a portion of the old tan from the surface; by this means the new tan is not suffered to come within a foot of the surface of the bed, and of course the pots are entirely plunged in the old tan. It is his general practice to deposit half of the quantity of new tan that may be added, in the bottom of the trench, and blend the other half equally with the old, till within a foot of the top of the bed. And in trenching over the beds, it is his custom to throw the sides to the middle, and the middle to the sides, in order that the old tan may be incorporated in an equal manner with the new.

It is contended, that in this manner of preparing the beds, they will be "of a mild and equal temperature from the first, and continue much in the same flat for three or four months, and that after the first filling, they will be attended with but little expense for new tan. It is obvious that the filling of the pits of new pincries, in the above intention, should either be performed some time before the plants are to be introduced, or the tan be well sweated down and reduced by frequent turning over in an open shed or other convenient place; and in these cases it is even advised not to plunge the pots more than half their depths into the beds for the first two or three months after they have been filled.

The new bark or tan that is to be added should constantly be thrown up into heaps for eight or ten days before it is employed, in order that it may drain and sweeten; as when wet, while from the tan-pit, it is apt not only to take in the beds, but sometimes to heat violently.

It is necessary, as soon as the beds have been made, to thrull flicks into the bark in different parts, in order that they may be drawn up occasionally to ascertain the heat of them.

The beds, in the first method of making them, will in general be of a proper temperature for the reception of plants in about ten days or a fortnight, as the examination of the flicks will shew. If they be intended for pines or other plants that require pots, they must be plunged immediately into the bark, no earth being necessary as in other sorts of hot-beds; and in performing this business, it is of utility to have a board placed across the beds or pits to stand or kneel upon, and thereby prevent the bark from being trodden too close. The pots containing the plants must be placed to suitable depths, according to the differences in the degrees of heat in the beds, in order to be lastly left down to their rims. When the heat of the bed is shown by the trying flicks to be on the decline, it will be proper to retire it by strirring up or turning over the bark, which, when of the large or middle sort, will seldom require any increase of new tan.

In accomplishing this business, it may be performed either in the manner directed above, or, after removing the pots, by beginning at one of the ends, and forking up the whole of the bark to the bottom, afterwards breaking the lumps and turning all the bark over, the pots with the plants being directly refilled. The same operation is to be repeated as often as the decline of heat may render it necessary, and such additions of fresh bark be made as may be required, but in common, not more than two or three turnings are requisite. The additions of fresh tan should modestly be made about the beginning of March or April, the crumbly earthy parts of the old bark being cleared away.

The making of new beds is mostly performed, as has been seen above, in the autumn, about September or October, as after they have remained ten or twelve months, the bark is much exhausted both in heat and substance, and becomes earthy. This earthy part is to be now separated by means of the screen, and new tan added, the whole being well blended together with the fork. When the whole of the old tan appears earthy, it is the best method to clear the pit out entirely, and make the bed up altogether of new bark. See Hot-House.

Bark-Borough, a disease which has been suppoed common to fruit and other trees, and to be capable of being cured by making a slit or opening through the bark, in a longitudinal direction, from the top of the tree or bough to the bottom, about February or March; and if the gape be properly considered, to fill it up with cow-dung, or some other familiar composition. This is probably not so frequently a disease as has been believed by gardeners, as the imperfect growth of trees often causes such appearances.

Bark-galling, is when trees are galled by thorns or by being bound to flake, &c. It is cured by clay laid on the galled place, and bound on with hay ropes.

Bark-Pit, a pit or cavity of a long, square, or other form, a yard or more in depth, appertaining to hot-houses and roofs, &c. and being formed internally, or detached externally, in which to make tan or bark hot-beds, commonly called bark-beds.

The dimensions are four, five, or six feet in width, or more, having length in proportion to that of the hot-house, &c. and when in detached pits. Such as may be required.
both methods they are formed by a low surrounding brick wall, about a yard in height in the internal pits, and in the external ones three or four feet in front, by four or five in the back wall. These different forms of pits are indispensably necessary, where bark-beds are intended, to make the beds in, as the front loose nature of the tan will not admit of being formed into such regular beds, without the aid of such kinds of enclosed pits to confine it close together within the limits that are requisite in the formation of the beds.

For various purposes, bark-pits are necessary in all hot-houses or stoves, and occasionally in forcing-houses, &c. And detached bark-pits, distinct from the hot-house, are likewise very useful in all extensive gardens on many occasions, being of great service in the culture of many sorts of tender exotics, and in raising various kinds under different methods of propagation; as well as for raising and nursing those of similar kinds in their young and tender growth; and also occasionally for forcing and raising early productions of several sorts of hardy plants in the greatest perfection.

The bark-pit of a hot-house, &c. is an essentially necessary interior compartment, and which, as before observed, is the internal cavity wherein the tan or bark hot-bed is made extended lengthways and occupying almost the whole bottom space of the house, except about two feet on each side and ends, which is referred for an alley or walk round, between the outward wall and that of the pit, which should be but very little sunk below the general surface of the floor of the surrounding walk, and formed by a thin wall of brick-work, generally railed, the greater part, three feet high above the surface, the bottom being paved with brick or stone, &c. and in which the bark-bed being made to the whole width, length, and depth, serves both to plunge the pots of the more tender exotics in, such as the pine-apple, &c. in order that they may receive the kindly moist heat thereof immediately about their roots; and, at the same time, to diffuse a peculiar beneficial warm vapour for heating the internal air, alluded to by fire-heat in the flies in winter, but insufficient alone in summer; producing, from May till October, an effectual temperature of internal heat, for the preservation and growth of various tender exotic plants of the fove, kind, natives of different parts of the hot regions of South America, Africa, Asia, and Africa. See BARK-BED, HOT-HOUSE, and STOVE.

Hot-houses, or fove of the common width, have in general only one pit; extending lengthways of them as described above; but if they are of considerable extent in length, the pit is sometimes divided in the middle by an intervening passage, to render it more convenient in performing the necessary culture of the plants.

Some hot-houses, however, of very great width, have two internal bark-pits ranging parallel lengthways with an alley or passage extending between them, which renders them more commodious in giving the requisite culture to the plants that are plunged in the beds, than if the whole was in one extremely wide pit, in which it would often be very inconvenient to come at the plants placed towards the middle of them; so that two parallel pits, four or five feet wide each, become more eligible than one of eight or ten feet, and by having an intervening passage, give a larger scope and afford a better current of air, for the growth of the plants in the beds, as well as admit of viewing them to greater advantage and effect.

Detached or external bark-pits are exterior erections, separate and distinct from the hot-house or fove, but in some manner connected with, or appertaining to them, being, on many occasions, employed for similar uses, as well as for various other purposes, where occasional artificial heat is wanted. They are, as has been observed, four, five, or six feet wide, having such length as may be required; formed by a surrounding wall of brick-work, three or four feet high in the front, by four, five, or six behind, where sometimes fices for winter fire-heat are erected in the upper part; the whole being covered at top with movable glass frames, facing in frontward to the full sun, and in which, a bark-bed being made to the whole width, length, and depth, becomes an useful appendage to the house; alluding in the culture of various tender exotics of that repository, especially in the way of a nursery-pit, for raising and preserving them to some advanced state of growth; also occasionally in the propagation and protection of the more tender kinds of green-house plants, or any particular, curious, or tender exotic plant, of the full ground, as being always ready and prepared with a continuing growing heat, wherein to plunge the pots, where artificial heat is required, or occasionally necessary in raising such tender plants more effectually and expeditiously.

These kinds of bark-pits also prove exceedingly useful in raising many sorts of tender exotics from seed, cuttings, slips, &c. and in retaining and forwarding them to the growth of their growth. In the case of the kinds of the same kind, are likewise particularly useful and necessary in the culture of young &c. pine-apple plants, in nursing and nursing them till of a proper age and size, to be placed in the fove, fove, or pinery. See BROMIELLA AANNES, and STOVE.

A similar kind of detached bark-pit is likewise occasionally used with advantage in the work of planting or transplanting, or shifting tender or curious plants in pots, for plunging the pots which contain them, as soon as re-planted, into which much expends their taking fresh root, and brings them up at first into a free and vigorous growth.

Bark-pits, of the same kind, are also successfully employed in the work of forcing and raising early productions, such as melons, kidney-beans, peas, strawberry, &c. and for many sorts of flowers, both of the bulbous, rooted, and herbaceous kinds, as well as for small flowering shrubs. And if the dimensions of them were increased, especially in height, in the back parts they might have several forms of dwarf-fruit trees in pots for the production of early fruit, placed in them. See CASTING-FRAME.

Detached bark-pits should always be erected in warm dry situations, in a southerly aspect, and be constantly ranged lengthways in the direction of east and west, or nearly so, in order to have the whole front inclined fully to the south, in a sloping manner, on which to place the flowers in the same position, being generally stationed either contiguous to the hot-house or fove, but at a proper distance in front of it, as the situation and convenience of the place may admit. Or they may be erected at one or at both ends, extending in a line with it, but separated by a passage between them.

But detached bark-pits are sometimes formed with ridged tops, like the roofs of houses, the glazed sloping to both sides, being ranged lengthways north and south, in order to have the benefit of the sun equally on both sides, and used for the same purposes as the others; though the common south-facing pits, extending east and west, are more generally adopted, being less expensive in glass-work, &c. and, in general, more convenient for different purposes of the forcing kind.

They should be constructed, as has been observed, with walls of brick work, forming the upright sides and ends nine inches thick; and where fire-flues are intended, the back wall should be of a proper thickness from the bottom, to admit of having flues in the upper parts, a fire-place being contrived externally at the bottom at one end; or, in consider-
filterably extended pits, a double fire-place may be formed in the middle, behind, or one at each end, either endways or in the back part, as may be thought the most convenient.

Some detached pits are formed of woodwork only, by means of post and plank; serving for particular occasions, where no fire-heat is required, as flowers for that purpose cannot be admitted in such kinds of pits; where additional fuel is occasionally necessary, in such pits, it is effected by applying a strong firing of hot dung to the outsides; by which a good constant heat may be supported. In these bark-pits, sometimes, the younger pine-apple plants are deposited and surfaced for the first year; they are likewise occasionally used for the purposes of propagating, raising, and nursing tender plants in spring and summer, &c.; also for forcing early eucalyptus, flowers, &c.

The principal detached bark-pits should, however, be formed with brickwork walls; as being the most effective for general use, and of the greatest duration.

At fig. 1. Plate 1. in Gardening, is the representation of a bed or pit of the most common kind, which may be made use of either with bark or dung.

Fig. 2. exhibits a view of a bark-pit upon a larger scale.

Fig. 3. is the plan and section of two nursing pits, as given by Mr. Niedl in the "Scientific Forcing Gardener," adapted equally to the purpose of forcing young pine plants, and the forcing of asparagus, cucumbers, melons, strawberries, French-beans, fallaids, flowers, &c. In the plan they appear considerably sunk below the ground level for the convenience of shifting, but in wet situations this should not be the case, but a bank of earth raised against them in a sloping direction all round, as by this contrivance the front flues may be useful in raising early fallaids, by having the front borders properly prepared. The furnaces are placed behind, communicating first with the front flues, but returning in the back, finely. The surface of the bark-bed is level with the bottom of the flues all round, to prevent the danger of burning; and at the distance of two feet from the wall of the pit. The inner wall of the flue is formed a brick on edge, and the outer one a brick in bed, for the purpose of strength. The divisions of the plan are only each thirty feet in length, but they may be extended to forty, and be wrought by the same furnaces.

One length of six is sufficient, as they are worked in the manner of the common hot-bed, having fallaings at top to prevent their slipping down.

Fig. 4. is the plan and section of a single pitted pine flue on an improved construction, as furnished by the same author for a fruiting or succeffion house. It is wrought by two fires, having a fixed behind it which may be converted to various uses.

The bottom of the bark-bed is level with the surface of the ground, but the surface much-levelled, that the sun and light may be admitted more freely to the plants.

Fires for vines may be placed against the brick-wall and upright flues in front.

Two lengths of flues are here necessary in the roof. The under ones should be made to move either up or down.

Fig. 5. is a bark-pit for succeffion pine-apple plants.

BARKARY denotes a tan-house, or place to keep bark in, especially for tanners.

It is otherwise called a breath-house in old writers.

BARKING of Trees, in Rural Economy, the operation of stripping off the bark or rind, which, when taken from some kinds of trees, as the oak, elm, &c. is made use of by the tanners, and of course becomes an article of profit to the proprietor.

It is the most usual in this climate to perform the operation in the month of May, as, at that season, the bark, by the rising of the sap in great quantity, is the most easily separated from the wood. This, however, renders it necessary to fell the trees in that month; by which the timber is of much less value than it would be if they were cut down after the falling of the leaf.

It is remarked by Dr. Darwin, in his "Phytology," that as the sap-juice runs in all deciduous trees during the vernal months to expand their foliage, though probably in greater quantity in some trees than in others; it must confit, not only of sugar and mucilage, as in the maple and birch, but of various other ingredients in different trees, which have not been attended to; as appears from the taste of their young leaves, as of oak or ash. And as some of these materials reside in the roots and sap-wood, or alburnum, to others of them may perhaps reside in the bark, where they have been deposited during the preceding winter, and become liquefied by the warmth of the spring, or diffused by the moisture absorbed from the earth and air, and conveyed upwards to the opening buds; whence it is evident, he thinks, that the barks of trees should be taken off for use in winter, or in early spring, before their buds begin to expand; as then a portion of these nutritious juices, or of the other materials which are required for medicines, or in the arts of dyeing and tanning, is in part expended on the young leaves, which generally pulfifes the taste and qualities of the bark, though in a few degree. It may nevertheless be observed, he says, that all these alluring or other materials may reside in the alburnum of the trunk or roots of all perennial vegetables, as well as in their barks; because the young leaves, which pullulate on decorticated oaks, have the same bitter flavour as the leaves on those which have not been decorticated; which may in part be derived from the bark of the root, which is still in the ground, and be carried up the vessels of the sap-wood to the new buds. Hence the bark of oak-trees should be taken off during the winter; but when the sap-juice, refilling or ascending in the vessels of the alburnum, becomes more liquefied by the warmth of the spring, or is mixed with moisture, and pulsed up with great force by the absorbent vellums of the roots, it comes out in some degree between the alburnum and the bark, and thus the bark becomes so much more readily separated from the sap-wood; whence this business, as has been already observed, is generally done early in the spring, and should always be performed as soon as this facility of detaching the bark appears; because this process of the generation of the buds continues to injure the tree, whether the tree be cut down or not; as the buds expand their foliage on new felled trees, while they lie on the ground.

It is observed by Mr. Marshall, in his "Rural Economy of Yorkshire," that the peeling of oak timber in that country is generally done by the day, the labourers being, he believes, invariably employed by the timber-merchant, not by the tanner; practices which are, he conceives, productive of a considerable saving of bark. Men, says he, working by the ton or quarter, or tanners paying by weight or measure, will not induce them to peel the branches sufficiently near; as it is against their interest to do it. But it is the interest of the timber-merchant, or of the tanner, if he purchases by the gross, or by the ton of timber, to peel so far or so long as the bark will pay for the labour. This, he thinks, accounts for the smallness of the twigs which are peeled in that county; if the bark run freely, twigs not much thicker than the finger are frequently stripped of their bark.

The tool commonly made use of for this purpole in most countries,
BAR

-countries, is made either of bone or iron. If of the former, the thigh or thin-bone of an afe is preferred, which is formed into a two-handed instrument for the flen and larger boughs, with a handle of wood fixed at the end. The edge once given by the grinding-done, or rasf, keeps itself sharp by the wear that afterwards takes place in the operation.

The method of drying bark in the above county is generally the common one of letting it in a leaning posture against poles lying horizontally on forked flakes. But in a wet season, when the ground is naturally moist, it is hid across a line of top-wood, formed into a kind of banklet, raising the bark about a foot from the ground. By this practice no part of the bark is suffered to touch the earth, and it is perhaps, upon the whole, the best practice in all seasons and situations. The bark is then put in flacks or houles, and generally shaved or chopped ready for the tan-pit, and afterwards sold to the tanner at so much the quarter. This custom, however, appears to be founded on a false basis; the tanner is the best judge of the mode of preparation, and the operation, ought, therefore, to pass under his immediate inspection.

The practice of grinding bark does not seem to have yet got sufficient footing in the district mentioned above; whenever it does, Mr. Marshall observes, it will of course bring the preparation of it into its proper channel.

The price of chopped bark varies considerably, according to the quality and the circumstances under which it is placed. Maliciously barking of apple-trees, or other fruit trees, is made felon by 37 Hen. VIII. c. 6.

By the French laws, all dealers are forbid to bark their wood while growing, on the penalty of 500 livres. This law was the result of ignorance; it being now found, that barking of trees, and letting them die, increases the force of timber.

BARKING is also a name given to the cry of dogs and foxes.

The term is also applied to certain quaint noises, made by sick persons in some diseases.

In cynic spasms, and epileptic fits, the patient sometimes snarles, howls, and barks, with all the notes of a dog. But it is in the hydrophobia that barking has been oftentimes observed; persons seized with this, are apt to rave, bite, foam, and make a harsh noise in their throats, which is called barking.—Vide Phil. Trans. No. 280. No. 323. No. 207.

And No. 242.

BARKING, in Geography, a market town in the county of Essex, seven miles from London, is so called from a creek on which it is situated. The town is of considerable extent, and chiefly inhabited by fisher-men, from whom the fish-markets of London are frequently supplied. The parish is divided into the four wards of Barking, Great Ilford, Chadwell, and Rippleward, abounding with fertile lands and beautiful prospects. It was to this place that William the Conqueror retired, shortly after his coronation, till he had erected such castles in London as might awe the people whom he governed; and here the great barons Edward and Morcar came and swore fealty. Very lately, the remains of an intrenchment were visible at this place; but the plough has nearly obliterated the whole. Much land in the parish has been recovered from the rivers Thames and Roding. The second number of the Saxons was founded at Barking by Erkineald, fourth bishop of London, in 666, for Benedictines; the bishop placing his father Ethelburga (afterwards canonized) as the first abbeys. She was constitution lady patroniz in all the monasteries within the half hundred of Becontice, and held of the king an entire barony, a privilege granted to only three other religious foundations in England, those of Wilton, Shaftesbury, and Winchester. At the dissolution, the revenues of Barking abbey were estimated at 862l. 12s. 5d. A gateway and a great part of the wall of this magnificent structure still remain adjoining the church-yard. In the township of Great Ilford is an ancient hospital for lepers. The parish church is a large handsome structure, which formerly belonged to the abbey, but is now in the gift of the warden and fellows of All Souls college, Oxford.

The market is held on Saturday, and a fair on October 22d for horses; another fair is held yearly on and round a famous oak denominated Fairlop, concerning which the following summary may be acceptable. Many years since, Mr. John Day, a worthy but whimsical character in Wapping, used annually to dine with his friends on lemons and bacon under the shade of this famous oak; hence arose the fair. Fairlop oak has sustained its dignity in the forest of Rainham for many centuries, and though it has very materially suffered, still maintains a majestic appearance peculiar to itself. About a yard from the ground, where its rough fluted stem is thirty-six feet in circumference, it divides into eleven vast arms, not in the horizontal manner of the oak, but rather in that of the beech. The fair held beneath its shade, which overspreads an area of 300 feet in circuit, has been injurious to the parent stem, by means of fires which the visitors have occasionally kindled in the cavities formed by the decayed roots of the tree. Mr. Ferlyth's composition, however, has in some degree remedied the decay; and a close fence five feet high, with a board on which is painted, "All good foresters are requested not to hurt this old tree, a plainer having been lately applied to his wounds," will, it is hoped, preserve Fairlop oak from further destruction.

BARKOW, a town of Poland, in the palatinate of Branlaw; 48 miles W.N.W. from Breslaw.

BARKU, a village in Africa, in the country of Agonza, where the Dutch have a fort. See AGONZA. Little Barku lies about a league and a half from the former.

BARKWAY, a populous and flourishing village of Hertfordshire, in England, is situated in the hundred of Edwindshire, three miles from Royton, 19 from Cambridge, and 34 north from London. This is a considerable thoroughfare in the road to Lynn, and has several good inns. At the time of the conquest, the lands here were divided between four great lords into as many manors. Barkway was an ancient market town, privileged by Ed. I. to keep a market on Tuesday, and an annual fair for five days. The market was altered in the reign of Eliza-abeth to Friday, and at last discontinued on account of its proximity to Royton. The church is a handsome spacious building, and the vicarage is in the gift of the Chetler family; within the building are several fine monuments and some curious painted glass. This village was greatly damaged by fire in 1738. Its houles amount to 147, and its inhabitants to 699.

BARLAAM, in Biography, a learned monk of St. Paul, flourished in the fourteenth century, and was born at Seminara in Calabria. Having in his youth visited Greece for the purpose of learning the Greek language, he settled at Constaninople in 1327, where he obtained by his extensive erudition the favour of the emperor Andronicus the younger, and also that of his confidential dominie John Cantacuzene, in whose house he resided. He was employed in teaching the languages and belles lettres; and in 1331, was made abbot of the monastery of the Holy Glied. Bar- lam is described by Petaruch and Boccace as a man of a di-minutive stature, though eminent for his learning and genius; of a piercing discernment, though of a slow and painful elocution.
Having visited the monks of mount Athos, he engaged with them in a controversy concerning the place of the soul and essence of God. These fanaticale sects, in their mental abstractions, pretended to see the light of mount Thabor, and were manifestly to the disciples in the transfiguration of Christ, a representation of the soul, conceived by them to be the seat of the soul; and this light was adored by them as the pure and perfect essence of God himself. Nor were these simple solitaries inquisitive, how the divine essence could be a material substance, or how an immaterial substance could be perceived by the eyes of the body. Barlaam ridiculed these monks, and accused them of hereby and blasphemy. His attack induced the more learned of the monks to renounce or dissemble the simple devotion of their brethren; and Gregory Palamas, who took a lead in this dispute on the part of the monks, introduced a scholastic distinction between the essence and operation of God. This distinction, however, did not escape the reproach of polytheism; and Barlaam charged the adherents of Palamas with holding two eternal substances, a visible and an invisible God. The dispute was violent, and Barlaam's life was in danger. However, he secured himself by a timely retreat; and Andronicus, who, with a view of obtaining the aid of the western princes against the Turks, wished to reconcile the Greek church with the fee of Rome, sent Barlaam, in 1339, to conduct this negotiation at the court of pope Benedict XII. at Avignon. Here he formed an intimate connection with Petrarch, whom he instructed in the Greek language; and Barlaam is said to have been the first who revived, beyond the Alps, the memory, or at least the writings of Homer. Being compelled, however, to relinquish a fruitful employment, he returned to Constantinople, and his dispute with the monks of Athos was renewed; and the censure of a council, held in 1341, obliged him to quit the city. After a separation of three years, he renewed his acquaintance with Petrarch in the court of Naples; and by his recommendation Barlaam was finally settled in a small bishopric of his native Calabria at Hieracium, now Gerace, where he died about the year 1348. He deputedly incurred the charge of inconstancy in religion; because, when he was a Greek monk, he wrote against the Latin communion, which he condemned after having been made a Latin bishop. Having adopted the sentiments and precepts of the Stoics, with respect to the obligations of morality and the duties of life, he digested them into a work entitled "Ethica ex Stoica." He also wrote a work on arithmetic, and some letters and orations. Mori. Gibbon's Hist. vol. xi. p. 588. vol. xii. p. 66. Molluin's Eccl. Hist. vol. iii. p. 305. 308.

Barlaamites, in Church History, the followers of the Calabrian monk mentioned in the preceding article. They are the same with those otherwise denominated Acin- dyntia. Barlaeus, Gaspar, in Biography, an eminent Latin poet of the 16th century, was born at Antwerp in 1584, and educated for the ministry at Leyden, where he afterwards settled in the exercise of his profession, and also as sub-professor and professor of logic. But in consequence of having joined the Armenian party, he was deprived of all his employments, and devoted himself to the study of medicine, for which purpose he took a doctor's degree at Caen. In the practice of physic, he made no great progress; but refuting the office of a tea her, delivered lectures in philosophy and the belles lettres to young persons at Leyden. From hence he removed in 1533, to the region of the university, in the public school founded at Amsterdam, where, on account of his attachment to Armenian principles, he was the object of jealousy to the orthodox, by whom he was unkindly treated, and unjustly charged with Socinianism. At length he fell into the hypochondriac maladies incident to literary men, and died in 1648. Barbaeus was a man of erudition as well as genius; and he principally distinguished himself by his Latin poetry, in which he has been thought to rival the ancients, and at least to be upon a par with Claudian. His "Poems," printed at Leyden in 1628 and 1631, contain three books of heroic pieces, two of elegies, and one of miscellaneous, consisting of abacisms, epigrams, &c. His Latin harangues, on various subjects, were admired. Every great event that occurred called forth his exertions; and he celebrated most of the greatest men of his age. His "Relation of the Transactions in Brasil under the government of count Maurice" was published in 1647; and his "Letters" were collected after his death, and printed in two volumes. He also published several controversial pieces, against the adversaries of Arminius. Gen. Dict.

Barlaeus, Lambert, the brother of the preceding, was born at Bommel in Guelders in 1595, and became professor of Greek in the university of Leyden. His inaugural oration "De Graecarum Literarum Praeclaria ac Utilitate," was pronounced in 1641. In 1642, he published the "Tition of Lucian," with notes; and after his death, which happened in 1655, his "Commentary upon the Theogony of Hesiod" was printed in 1658. Gen. Dict.

Barlaimont, of Barleman, in Geography, a town of the Netherlands, in the county of Hainaut; 4 leagues southeast of Le Quefnoy.

Barland, Adrian, in Biography, a writer of the sixteenth century, was born about the year 1488 at Barland, a village of Zeeland, whence he took his name. Having studied at Ghent and Louvain, he became first a private teacher at the latter place, and afterwards professor of eloquence in the university; in which station he continued till his death in 1642. His works, which were all written in Latin, were numerous. Some of the principal are "Notes on Terence, Virgil, Menander, and Phily the younger;" "An Abridgment of Universal History, from the birth of Christ to 1532;" "On the Doges of Venice;" "Chronicle of the Dukes of Brabant;" "History of the Counts of Holland;" "Life of Charles, Duke of Burgundy;" "Catalogue of the chief towns of Lower Germany;" "De literatis Urbis Romae Principibus." Several of his historical works were published together at Cologne, in 1603, 8vo. Moreri.

Barlanga, in Geography, a small island, is the principal of a cluster in the Atlantic ocean, about 3 leagues from the west coast of Portugal, with a fortress. These islands are called "Borings" by the English seamen, and all of them are merely rocks. N. lat. 39° 20'. W. long. 8° 41'.

Species, 1. **D. jagishana**. Anacoura. Pluk. Alm. 30. 1. 133. f. 4. Morr. 3. 11. f. 27. f. 5. "Spines of the whoro's fixfold; leaves eniform, very long, seabrows." The stem is erect, rough, obtusely quadrangular; leaves opposite, lanceolate-sword-shaped, entire, three to five times the length of the internodes; flowers in whorls, axillary; three spikes on each side of the stem of the length of the whorls. A native of the East Indies. Introduced here by Sir J. Banks, in 1781. 2. **B. johnsonii**. Plun. g. 51. 52. f. 1. "Spines axillary; leaves lanceolate, 'teeth-bloted." Stems erect, square, three feet high, with two oblong entire leaves at every joint, above which the flowers stand in whorls, surrounding the stalks, and under each whorl are fix sharp spines as long as the calyx; the flowers are blue, and more completely labiated than the other species of the genus. 3. **B. Hybrida,** hybrida frutes. Rumph. 7. 22. 13. "Spines axillary, twin, simple; leaves entire, lanceolate-ovate." Stem wand-like, not firm; branches scarcely angular; leaves smooth on both sides; axillary spines twin, simple, fimbrij, horizontal. A native of the East Indies. 4. **B. Priorii.** Coetla-Veetla. Rheed. Mal. g. 7. 41. "Spines axillary, pedicu, fourfold; leaves entire, lanceolate-ovate." Stem herbaceous, round, rift; leaves opposite, running down the petioles, pubescent underneath; between the branch and leaf a spine, with four sharp rays from the centre; calyxes acuminate-fimbrij. A native of the East Indies. 5. **B. Roxburghii.** Carachhuli. Rheed. Mal. 2. 91. 17. "Spines axillary, opposite, foliari; leaves roundish, dill." Stalks furcibly, five or fix feet high, with strong spines under the leaves; flowers in whorls towards the upper part of the foot; seed-vell is short, containing three or four flat seeds. A native of Jamaica and the East Indies. 6. **B. mésiira.** "Spines axillary, branchmg; leaves lanceolate, entire, cupdated; bracte ovate, fimbrij; tube elongated." Flowers blue, resembling those of B. buxifolia, but longer, and expaining during the night; bractes smooth. Observed near Tanjour by Koenig. 7. **B. retiflora.** Melanpyro cognata, &c. Mor. Hill. 3. 427. f. 11. i. 23. f. 7. "Leaves oblong, entire; two kaffets of the calyx broader, dilated, and two linear, acute." Stem round; leaves oblong-ovate, sharp at both ends; flowers axillary, fimbrij; two leaves of the calyx ovate, acuminate, fimbrij; two alternate, shorter, linear, acute, entire, spreading or cordate, blue, with ovate lobes. 8. **B. corenica.** Plun. g. 51. 52. f. 1. "Unarmed; leaves ovate, tooth-bitted, petioli." Stems smooth, four feet high; flowers scarlet, in whors at the joints, and appearing from July till September. A native of South America. 6. **B. purpur.** "Unarmed; leaves ovate, acute, purpure; bractes ciliate." Found at the Cape of Good Hope by Thunberg. 10. **B. ligust.** Gaertn. Flav. 255. "Unarmed; leaves ovate, fimbrij; bractes cordate, fimbrij; corollae very long." An underhbrb, with opposite fimbrij branches; leaves opposite, entire, on fimbrij; flowers terminal; bractes two or bivalve, fimbrij, nearly as large as the leaves, and below these four other bractes dissected crenate-wihe, linear, spreading, fimbrij, as long as the leaves; capulse pointed at each end, quadrangular; seeds much flattened, covered with waved bundles of opprilled hair. Found on the mountain of St. Thomas in Malabar by Koenig. 11. **B. auriculata.** Lour. Cochlin. 357. "Unarmed; leaves lanceolate, crenate, bifimbrij; heads terminal." This is a procumbent twisted round underhbrb; leaves opposite, broad-lanceolate; flowers yellow; bractes acuminate, ciliote; segments of the calyx subulate, hairy; capsule oblong, angular, with orbicular seeds. A native of China, near Canton. **Propagation and Culture.** All the species of this genus require the protection of a bark-florc. The second, fourth, fifth, and eighth were cultivated by Miller, but the others have not yet been introduced here. The second is to be propagated by seeds, which will sow themselves in the pots which are near them in the flower, when the plants are once obtained; but when the seeds are received from abroad, they must be sown on a hot-bed on the spring; and when the plants are fit to remove, they must be each planted in a separate pot, plunged into a hot-bed of tanners' bark, where they must constantly remain, and be managed in the same manner as other tender exotics from the same countries; giving them water frequently in summer, and allowing them fresh air every day in warm weather. They flower from June till November. The fourth has flexible perennial stalks, which, if cut off during the summer months and made into lengths of six or eight inches, and planted in pots, putting them into hot-beds, and duly watered and shaded from the sun, will soon put forth roots, when they may be each planted in a small pot and plunged into the tan-bed in the flower, where they are found to grow better than in the dry flower. This species rarely produces flowers in England. The fifth and eighth ports will produce seeds which are to be treated in the same manner as the former. See Martyn's Miller's Dic. **BAR**

**BARLETTA,** in Geography, a sea-port town of Italy, in the kingdom of Naples and country of Bari, on the Adriatic, four miles west of Trani. The site of this city is magnificently built, though it has from without a ruinous aspect, and is thinly populated. Frequent changes of masters, bad administration, and decay of commerce, have blasted its prosperity. Its streets are wide and well paved, and its houses large and lofty. The style of building fixes their date at the first emergence of the arts out of the chaos of barbarism; many of the houses still retaining pointed arches, short twisted columns, and other remains of Saracenical taste; while others are decorated with pillars, entablatures, and members characteristic of the ancient Grecian architecture. The city owes its embellishments to the policy of the Arragouna kings, who resided here to secure the allegiance of the Puglies. In the cathedral, which is remarkable for its antique granite columns, Ferdinand I was crowned. In the market-place stands a colossal bronze statue, fourteen feet three inches high, representing, as it is supposed, the emperor Heraclius, who began his reign in 610. The citadel is spacious, and commands the port, consisting of several irregular piers, but without any shelter from the north wind, which sweeps the whole baken. The exports from this place are salt, corn, almonds and liquorice, which latter grows spontaneously in the swamps. During the hot months the air is accounted unwholesome. Barletta is said to have derived its name from a tower, or drinking-hourse, situate on the road to Canne, having for its sign a barred," barilletta;" and when the cities of Canne and Canosa fell to decay, and the advantages of trade drew people to the coast, a numerous colony gathered round this tower, and in 484, pope Gelasius consecrated a church for the settlers, which became the cathedral of the united cities of Nazareth, Canne, and Montevideo. The emperor Frederick added greatly to Barletta, and has been by some called his founder. Others suppose it to have been the Bardali of the Itineraries. In the fifteenth century, Barletta was acclaimed one of the four strongest fortresses in Italy; the other three being Fabriano in the Marche, Pereto in Tuscany, and Crema in Lombardy. Swinh. Trav. vol. i. p. 275. N. lat. 41° 30'. E. long. 16° 32'.

**BARLEY,** in Botany, a gramineous, frumentaceous herb, whose seeds are of the largest fort, being covered with a hull, growing in a spike, and the grains bearded. See Hordeum.
BARLEY.

Pearl Barley, and French Barley, are barley sown from the hulk, and rounded by a mill; the distinction between the two being, that the pearl barley is reduced to the size of small flint, all but the very heat of the grain being ground away. In mills appropriate to this purpose, the mill-stone is round, the circumference of the edge of an under stone, and below it a wooden base, in which it revolves, and which, on the inside, is lined with a plate of iron pierced like a grater, with holes having their sharp edges turned upwards. The barley is thrown upon the stone, which, as it runs round, draws it in, frees it from the hulk, and rounds it; after which, it is put into sieves, and sifted. The first kind of barley-mills is a German invention. In Holland, the first was erected at Saardam, not earlier than the year 1660. This mill, which was at first called the Pollekkaan, fearcely produced in several years profit sufficient to maintain a family, but in the beginning of the last century, there were at Saardam fifty barley-mills, which brought considerable profit to their proprietors.

Barley, in Agriculture, a well-known kind of grain from which malt is made. Miller enumerates four different sorts of this useful grain: spring barley, long eared barley, short barley, and winter barley.

The spring barley has a double row of beards or awns flanging erect. This is the sort principally cultivated in the southern and eastern districts of both England and Scotland, and which the farmers distinguish into two different kinds, the common and the rath-ripe barley; but the two sorts are in reality the same, as the rath-ripe is only an alteration of the common barley, occasioned by being long cultivated upon warm gravelly soils. The seed of this, when sown on cold or strong land, will, the first year, ripen nearly a fortnight earlier than that taken from strong land, and therefore the farmers in the low districts generally procure their seed barley from the warm or gravelly lands; and when cultivated in the vales two or three years, it becomes full as late in ripening as the common barley of their own produce; on the other hand, the farmers on warm gravelly lands are obliged to procure their seed barley from the strong lands; otherwise their grain would degenerate in bulk and fulness, which by this change is prevented. This sort of barley is easily distinguished as above, and besides the rind is much thinner, and of course it is esteemed better for making malt.

The long-eared barley is likewise cultivated in many parts of England, and is a good sort; but some cultivators object to it, because from the ears being long and heavy they think it more apt to lodge. In this sort of barley, however, the grains are generally ranged in a double row, lying over each other, like the tiles of a houfe, or the scales of fish. It has no beards or awns; and its rind is very thin; and therefore it is esteemed better for making malt.

The short barley, which is sometimes also called Battadore, Fulbany, and Peising barley, from great quantities being cultivated in the neighbourhoods of those places, has thinner and broader ears than either of the former sorts; the awns or beards are longer, which tend greatly to preserve it from the birds, and the grains are placed together. It seldom, however, grows so tall as the other kinds; the straw is generally coarser, and therefore not so good as fodder for cattle.

The winter barley, which is called also square barley, bear barley, and big, is seldom cultivated in the southern parts of England; but in the northern counties, and in Scotland, it is the sort generally sown, as being much harder than the other sorts. There are two kinds of this barley, the one with four rows of grains, and the other with six, the latter of which is commonly distinguished by the name of barley big. The grain is large and plump; but the rind and chaff of it being thicker than that of either of the preceding sorts, it is less esteemed for making malt.

Barley, from its being that sort of grain which is confiderably next in value to wheat, is very generally cultivated. On dry, light, mellow, fertile, the thinnest, and largest-barled barley, which is always esteemed the best is quality, is produced. Even light poor soils, when dry, and from nature and situation warm, yield barley which is superior in quality to that which is commonly reaped from the strongest land when cold or of a moist nature.

In the corrected report of Middlesex it is observed, that the tender nature of this plant, in its infant state, unites it for cold and compact soils. It thrives best in a soil that is moderately dry and light, as a loamy land, and is esteemed rather a clean crop. As, for this crop, the soil is generally well tilled, late in the spring, it reduces the weeds very much; and from its occupying the ground only four months, they have not time to recover themselves and perfect their seed. This grain may and frequently is, the writer says, sown after every kind of crop, but always succeeds best after turnips, peas, beans, or others of an ameliorating quality.

In the preparation for this grain, the soil should invariably be well pulverized and rendered light, first by a thin ploughing and then by harrowing, which should be followed at as great a distance as the seafon will admit by a more deep crofs ploughing, harrowing, and rolling. The seed should then be ploughed in with a very small furrow, and immediately afterwards clover seed harrowed in with short-tined harrows, which leaves the land as light as possible. The next thing to be done is, with one horse to draw a very light roll over the land, in order to pres the mould gently on the seeds. These operations promote a more certain, speedy, and equal vegetation than can be procured by harrowing in the seed. Harrowing in the seed is, however, the more usual method, and is, he thinks, the cause of much grain being lost, and also of the crop being often of two or three growths. Many farmers potspone the last rolling until the first leaves of the seeds are up, but, it is believed, more from the hurry of the seafon than from choice. This perfect tilage seldom fails to secure a good crop of barley, and a plant of clover.

In the event of land-springs, or excessive rains, it may be advisable not to plough the land flat, but into ridgelets of about eighteen inches wide. These will drain themselves dry in any weather, at least so much so, that two or three dry days will prepare the soil for harrowing previous to the second ploughing; and if the seafon should fill continue favourable, the land on such second ploughing might be laid up in a similar manner till fowing-time; when two or three days more of fine weather would render it fit to be harrowed or scuffled down, and for ploughing in the seed: otherwise a third ploughing may be given, and the seed be harrowed in; which last is considered the better practice, where the soil is not quite so dry as could be wished. Scuffing the land, instead of the second ploughing, would in fine seafons dispatch the work, and be a saving of expense. In the clearest soil it would be equal to crofs ploughing, and in soils not quite free from root-weeds it would be much more useful by bringing them within reach of the harrows. It will perform more than double the quantity of work with the same number of men and horses, and leave the land equally ready for the harrow and roller before fowing the seed.

The author of the Synopsis of Husbandry observes, how...
ever, that it is improper to sow clover among barley on rich land, because the natural fertility of the soil haints on the vegetation of the grass, which will before harvest have advanced to a considerable height among the corn, and will occasion a longer time to be necessary for drying the straw; and thus, by lying abroad longer than would otherwise have been required, a total destruction of the crop may ensue; but in those lands, where there is not the danger of fo luxuriant an increase, clover, trefoil, and other grass-feeds may; he thinks, often be sown among barley; and if a favourable time can be procured for harrowing it, the flame may be greatly improved by the mixture of the clover or other grass, and become then a valuable fodder in the winter; but barley-straw simply is, he says, the most ordinary cattle-food of any.

Where barley succeeds turnips, the land is sometimes only once ploughed; but the author of modern agriculture says that it is a much better method to plough it twice, first early in the spring, and again before sowing the feed. This haft is the practice in Norfolk, where that species of grain is cultivated in a more perfect manner and to a greater extent after turnips, than perhaps in any other district. But when barley is sown after peas, beans, or oats, the land is commonly first ploughed in autumn; and the attentive farmer always takes care on this occasion to plough in such a manner as to expose as great an extent of surface to the influence of the air and frost as possible, and at the same time to form the ridges in such a way as to prevent the field from receiving any damage from excessive rains during winter. The second ploughing is given immediately after the oat-feeding is finished. This ploughing is intended to answer two purposes; in the first place, to loosen the couch-grasses and other root-weeds where they abound, so that they may be easily taken out by the harrows, which are immediately afterwards applied; and in the second place, to reduce the foil to a finer tilth, whereby the feed-weeds are encouraged to vegetate, and which the subsequent ploughing and harrowing at feed-time effectually destroy.

This sort of grain is also frequently sown after wheat, when the same mode of culture as just mentioned is adopted. But however common this rotation of cropping may be in some districts, there is no good reason, he says, why it should not be recommended to the general notice of farmers. For two white corn crops succeeding each other is undoubtedly an erroneous method, both for profit and improvement. Besides, it mostly happens, that where barley succeeds wheat, the crop is in some measure blighted, many of the stalks becoming white about the month of July; and where there are any grains in the ears, they are shrivelled and never come to maturity, though the soil may be well suited to the production of this sort of grain.

The author of the Survey of Middlesex indeed thinks, from the nature of corn crops, that barley ought not on any account to be sown after either wheat, rye, or oats; a much better practice being to sow it after turnips, potatoes, carrots, peas, &c. and in some cases, after hemp, flax, and rape. The land should not receive any further manure than what was laid on for the preceding crop, together with the dung and urine deposited by cattle during the time they are eating the green crops off the land.

The feed fowings for barley begins, in most of the southern counties, about the first week of March, and terminates in the more northern ones, towards the middle of June. But from the middle of March to the end of April may be reckoned the chief barley feed fowings, as within these periods by much the greatest proportion of that species of grain is put into the ground.

The author just mentioned observes, that barley, though usually sown during the months of March, April, and May, has succeeded when put in the first week in June; but it ought to be sown as early as the soil is sufficiently dry and in condition to receive it, and the prior attention which is due to the oat, tare, and other crops will permit. Let it always be kept in mind, says he, that barley will bear late sowing much better than those crops. Both the four and fix-rowed kinds of barley are frequently sown in the autumn nearly at the same time with wheat, not only in temperate climates, but also in very cold countries; their hardiness being such as to bear the severity of the winter season even in the mountainous parts of the northern countries. In hot countries, they are most frequently sown in January, February, and March.

All the other fowings are sown in the spring of the year in a dry time, as has been already seen; when this sort of grain is sown late on strong chayes soils, if the season does not prove very favourable, it is very late in autumn before it is fit to reap or now, unless it be the early or rath-rip fowings, which is often ripe in nine weeks from the time of sowing.

In the seventh volume of the Annals of Agriculture, Mr. Young gives the following experiments by Mr. Macro, on early and late sowing of barley; on November 17, 1785, he began his experiments by sowing two bushels of barley, which he harrowed in on clover land that had been folded the fame as for wheat; the first sowing, therefore, had only one earth. The barley came up about a week sooner than the wheat by the side of it, which was sown the fame day, and was exceedingly flourishing till the first sharp frost set in, which damaged the blade, but did not seem to affect the root. As near the middle of December as the weather would permit, he fowed two bushels more, on exactly the fame quantity of ground, and some about the middle of every month, till the month of May 1786. This and every fowing after, it had two earths; one call, or half the feed, was ploughed in, and the other half harrowed in; all the land was folded alike in the month of November. The second sharp frost killed some of this fowing, and a good deal of that sown in November; but they both, with that fown in January, fowed to fuller fill more by the sharp cutting winds in the month of March, when there was no snow to cover the blade, and it was injured by the frost. The sowings in February and March loft few, if any of their plants, and, what was somewhat remarkable, were both forward enough to be harvetted on the fame day with the three preceding sowings. That fown in April was full a fortnight later; and that fown in May, there not being any fo late fown in the neighbourhood, was entirely destroyed by vermin.

As he some years before intended trying the fame experiment, but was disapponted of knowing the event by the slpidity of his workmen, he determined this time to prevent any mistakes by mixing the different parcels in the barn, to threfh enough of the different sowings in the field to satisfy himself which was the most profitable crop, and accordingly attended the threfhing the whole day himself. As it was not at all necessary for the experiment to threfh the whole crop, he took three twathes of each sowing twelve yards in length, on the lowest part of the land, where he thought the soil was the most equal for the purpose of the experiment, which, he should have observed before, were by the side of each other on the fame piece of land. He had every parcel drefled and put into a fack by itself as soon as threfhed, and the account f/feed thus:

From
BARLEY.

The last fowling, as observed above, was entirely destroyed by the rooks; he believes it had not been flown more than three days before they began to scrape and pick it up, and completely devoured it. It was the fame with the very early fowlings, but that he expected, and was guarded against. It may however serve he thinks, as a lesson to farmers, that although early flying may in most cases be profitable, yet it will not answer in large open fields, where the lands are intermingled, unless neighbours low at the same time; for, if only one farmer fows early, he must have as many keepers as he has pieces of land. The barley of all the fowings was of the Zealand rock.

On the fame piece of land on which he tried the above experiments, which was a deep land, value about fix or leven shillings per acre, he tried two others, one about ten years fince, with chalk from different pits, fame of which was a dry chalk, and others greyly; he carried only one load of each, and laid it about the thickest of seventy loads to an acre. Neither of them did the leaf good, for he could not tell by any of the crops fince, without looking at the foil, where they were laid. The other was by deep ploughing, in the autumn of 1785, when he fowed part of the piece with wheat, by going with a fercond plough after the first for one ferch only, and tilling about three or four inches of foil that had never been turned up before; on viewing it about midsummer he could not find where it was by any apparent difference in the crop, nor could he fee that the barley fown in January was the best crop. By the fame rule, when he began to try the experiment before, that fown in February was the best, and it appeared fo on view, he remembers, all the farmers.

The quantity of feed barley allowed to the acre varies very much; and depends not only on the quality of the land and the fenafon, but on what was the preceding crop, and also on the condition of the land for receiving the feed. When barley succeeds turnips, the land being then in the best state for the feed, a lefs quantity is necessary than if it were to be fown after two or three succesfive white corn crops. The ufual allowance to the acre is from three bufhefs and a half to five; but four bufhefs and a peck may be confidered as the general average, fo large a quantity as five bufhefs being never sown but on lands exhausted and worn out by improper cropping.

Mr. Middleton remarks (in his Survey of Middlefex) that early fowling requires lefs feed than late; but on a medium foil in proper condition, fown bread-calf, in March three and a halt, in April four, and in May four and a half bufhefs per acre are fufficient. A rich foil makes fuch a great difference, that it can hardly be fown too thin; even one bufhef and a half early fown, has produced as much as could fland; whereas had three or four bufhefs been fown, the crop would have been lodged, and of a very reduced value.

It is obferved by Mr. Donaldfon, that if a statement of the average returns of barley by the acre was confided to England and the south of Scotland, it might be avered at thirty-two bufhefs; but when Wales and the north of Scotland are included, where, owing to the imprefed modes of fulture f still practifed, the crops are very indifferent, the general average over the whole will not probably ex-ceed twenty-eight bufhefs the acre. The author of the Agricultural Report of Middlefex states it as varying in England from fifteen to feventy-five bufhefs per acre. The average produce of the county of Middlefex, he fays, is about four quarters of corn and two lands of straw per acre. The straw usually fells at about a guinea a land delivered in, which, with chalk and thin grain, is equal to one bufhef and fixpence per bufhef on the corn; and as the corn has averaged three shillings, together they produce four shillings and fixpence per bufhef, or seven pounds four shillings per acre.

The ultimate defination of barley to be converted into beer and spirits, he fays, raises the value of this crop to more money per acre than that of any other grain. For after the farmer has disposed of it, the maltier, brewer, difiller, rectifier, and victualler, fucceffively draw the wages of labour and profit from it before it comes to the confumer. Including a revenue of five millions and one quarter a year, which it nets to government, but which costs the fubject between fix and seven millions, its entire expence to the confumer at this time is not lefs than thirty pounds an acre. He understands that porter is brewed in the ratio of 162 gallons from one quarter of malt: and is sold by the retailer after the rate of one shilling and two-pence per gallon, which produces nine pounds nine shillings; deduct the value of the hops, and there remains upwards of a guinea a bufhef for the malt, or full thirty pounds an acre. In the article of spirits, he thinks, it must necessarily yield much more. According to Mr. Donaldfon, barley is applied to various uses. In Wales, Weftmoreland, Cumberland, and in the north, as well as in several parts of the west of Scotland, the bread ufed by the great body of the inhabitants is made chiefly from barley. Large quantities of the barley cultivated in England are converted into beer, ale, porter, and what is called Britifh spirits, as English gin, English brandy, &c. The remainder, beyond what is neceffary for feed, is made into meal, and partly confumed in bread by the inhabitants of the above districts, and partly employed for the purpofe of fattening black-cattle, hogs, and poultry. There is a much greater care of the Scotch barley confumed in defillation in proportion to the quantity cultivated, than there is in England. Exclusive of what is ufed for feed, the Scotch barley is either converted into beer or ale; or made into pot barley, or into meal, for the ufe of the inhabitants in the more remote and lefs cultivated parts of the kingdom; or, laftly, into whiskey.

In the Report of Middlefex it is also stated, that much of the moft ordinary barley is given to poultry; the reft is fold to the maltiers, except fo much as is reserved for feed. In refpect to pearl barley it is observed, that a mill to manufacture it coûts about twenty pounds. A ton, or 160 flone, of pearl barley fells for twenty three pounds, which is rather under three shillings a flone, or thirteen shillings and four-pence a bufhef. Twenty-three flone and a half of common barley produces five flone and a half of pearl barley by the common method of manufacturing it; but by an addition to the mill, which would only cof two pounds, the barley corn would be split, and then the fame quantity would yield nine flone of pearl barley. This is fated on the
the authority of evidence before a committee of the London Society of Arts.

With regard to the choice of seed barley, it is necessary to observe that the best grain for sowing is that which is free from blackened at the tail, and is of a pale lively yellow colour, intermixed with a bright whitish tinge; and if the rind be a little shrivelled, it is too much the better, as it shows that it has sweated in the mow, and is a sure indication that its coat is thin. The husk of thick-rinded barley being too stiff to twist, will be smooth and hollow even when the inlaid flour has shrunk from it.

The necessity of a change of feed from time to time, by sowing that of the growth of a different foil, as has been observed, is in no instance more evident than in the culture of this grain, which otherwise becomes coarser and coarser every year. But in this, as well as in all other grain, the utmost care should be taken that the feed be full bodied.

It is easy to suppose that barley, like wheat, may be benefited by being steeped before it is sown. For as rain cannot always be depended upon soon after the sowing of spring corn, there is surely an equal reason for extending the practice to these sorts of grain as well as those which are sown in autumn. Liming indeed may hurt barley in some cases, but a little sprinkling of foot bids fair for improving it, at least it may prevent infects from preying upon the feed.

Mr. Fielden indeed remarks, that the feed is never steeped, and yet the farmers are continually complaining of its coming up at different periods, thus producing two crops which do not become ripe at the same time, and are injurious to the sample. Steeping the feed a proper number of hours, which might be ascertained by experiment, seems (he says) to be as well calculated to secure an uniform vegetation and prevent this complaint, as poising the feed appears to be to keep it from vermin.

According to Miller, the common method is to sow the barley-feed with a broad-cast at two fowings; the first being harrowed in at once, but the second not until the feed is buried. The common allowance of feed is four bushels to an acre: but (says he) if the farmers could be prevailed upon to alter this practice, they would soon find their account in it; for if a third part of that quantity be sown, there will be a much greater produce, and the corn will be much less liable to lodge, as he has many times experienced; when corn or any other vegetable lands very close, the stalks are drawn up weak, and thence incapable of resisting the force of the winds, or supporting themselves under heavy rains; but when they are at a proper distance, their stalks will be more than twice the size of the other, and therefore are seldom laid. He says he has frequently observed in fields where there has been a foot-path through their middle, that the corn which has hodd thin on each side of the path has hodd upright, when all the rest on both sides has been laid flat on the ground; and whoever will give himself the trouble to examine these roots near the path, will find them fuller, that is, have a greater number of stalks, to more than four times the quantity of the other parts of the field. He has been experiments made by sowing barley in rows across divers parts of the same field, and the grains hodd thin in the rows, so that the roots were three or four inches asunder in the rows, and the roots a foot distant; the intermediate spaces of the same field were at the same time hodd broad-cast in the usual way. The successe was this: the roots which hodd thin in the rows, tillered out from ten or twelve to upwards of thirty stalks on each root; the stalks were stronger, the ears longer, and the grains larger, than any of those hodd in the common way; and when those parts of the field where the corn was hodd in the usual way have been lodged, those parts hodd thin have supported their upright position against wind and rain, though the rows have been made not only lengthways but across the lands in several positions, so that there could be no alteration in regard to the goodness of the land, or the situation of the corn. Where therefore such experiments have been made, and always attended with equal success, there can be no room to doubt which of the two methods is most eligible. Indeed, if the crops were only supputed to be equal in both, the saving two thirds of the corn hodd is a very great advantage, and deserves a national consideration, as such a saving in scarce times might be of very great benefit to the public. This saving of feed-corn (says he) must be understood to regard such as is hodd broad-cast; for if it be hodd in drills, an eighth part of the feed usually hodd will be sufficient for an acre of land, and the produce be greater; for all sorts of corn are naturally inclined to send out several stalks from each root, which they rarely fail to do where the roots are at a proper distance and have room; nor do the stalks grow in this case near so tall, but are much stronger than when they are near together, when they rarely have more than two or three stalks, whereas those roots which have proper room seldom have less than ten or twelve. He has had eighty stalks upon one root of barley, which, by their weight pressed the stalks of the other, and the grain was better filled than any he ever saw grow in the common method of husbandry, and the land on which this grew was not very rich; but he has frequently observed on the sides of hot-beds in the kitchen gardens, where barley straw has been used for covering the beds, that some of the grains left in the ears have dropped out and grown, the roots have produced from thirty to sixty stalks each, and those have been four or five times larger in size than the stalks ever arrive at in the common way. But to this, he knows, it may be objected, that although upon rich ground in a garden these roots of corn may probably have fo many stalks, yet in poor land they will not have such produce; therefore, unless a greater quantity of feeds be hodd, the crop will not be worth fianding; which is (he says) one of the greatst fallacies that can be imagined; for to suppose that poor land can nourish more than twice the number of roots in the same space as rich land, is such an aburdity as one could hardly suppose any perfon of common understanding guilty of: and yet so it is; for the general practice is to allow a greater quantity of feed to poor land than for richer ground; not considering that where the roots stand fo close, they will deprive each other of their nourishment, and consequently starve themselves, as is always the case when the roots stand close, which any perfon may at first sight observe in any part of the fields where the corn happens to scatter when they are sowing it: or in places where by harrowing the feed is drawn in heeps, those patches will starve, and never grow to a third part of the size as the other parts of the same field; and yet, common as this is, it is little noticed by farmers, otherwise (says he) they would not continue their old custom of sowing. He has made many experiments for several years in the poorest land, and has always found that all crops which were hodd or planted at a greater distance than usual, have succeeded best upon such land: and he is convinced, if farmers would be prevailed upon to quit their prejudices and make trial of the method of sowing their corn thin, they would soon see the advantage of this husbandry.

The experiments of Mr. Young, however, lead us to a different conclusion. On April 25th, 1791, upon a land of moif loam on a wet marl bottom, worth about sixteen shillings an acre, he marked four beds, each eight feet long
long by three feet broad, and dibbled them with four-rowed barley.

No. 1, 91 holes, and four seeds in each hole.
2. 198 ditto, three seeds in each.
3. 198 ditto, one seed in each.
4. 198 ditto, two seeds in each.

No hoeing given; but before they ripened a net was suspended over the whole, to guard the barley from the ravages of birds.

On Sept. 9th he reaped them, and clipping off the ears, weighed them.

No. 1, 28½ ounces.
2. 31.
3. 20½.
4. 24.

In No. 1, 13 grains of seed give one ounce produce.
2, 19 grains of seed, one ounce produce.
3. 9½ ditto, ditto.
4. 16½ ditto, ditto.

In No. 1, 17 grains of seed per square foot.
2. 24 ditto, ditto.
3. 8 ditto, ditto.
4. 16 ditto, ditto.

It seems (says he) remarkable, that comparing No. 1 and 4, the seed are nearly same, yet the crop is different, and very considerably in favour of the seed being crowded together in clutters, rather than spread much more equally over the ground. This (continues he) is a most singular circumstance; it coincides very much with the modern practice of dibbling wheat, which has been changed gradually from one grain in a hole, to two, three, and even four, and this clatter-fowing has been found to answer best. But upon what principles? and owing to what cause? Theory would seem to tell us, that plants flanding close would have regular spaces for the roots to feed in, without struggling with each other for nourishment; but there must be some other circumstance which more than balances this advantage. The farmers say that the plants siffit each other: but how? Is it by shelter? it is by an accelerated fermentative motion from additional warmth? Very obscure all this, but highly deserving further repeated and varied experiments. Mere quantity of seed appears to have much effect; No. 2, the malt feed, has of all the greatest crop.

It is a common practice in some parts, to scatter the dung of pigeons, poultry, &c. over barley and other grain after they are fown; but if this method be purified, care should be taken to scatter such dung on immediately, because then the shoot will easily make its way through; but when laid on later, it is apt to burn up and deftroy the blades of the young plants.

It often happens, on the more stiff soils, from unfavourable weather and an extremely dry spring, that it is impossible, by the common method, to break the clods and prepare the ground sufficiently for fowing barley; in which case it has been the usual method to break the clods with a large beetle, called from its ufe a clatter-beetle: but this being a very expensive and tedious method of preparing land, induced the ingenious Mr. Randall of York to construct an instrument, which he calls a Jokly roller, by the assistance of which a large quantity of land may, in such a dry season, be soon reduced to an exceeding line tilth, with very little trouble. See Spike Roller.

After the barley is fown and harrowed in, the ground should be rolled after the first shower of rain, to break the clods and lay the earth smooth, which will render it easier to mow the crop, and also cause the earth to lie closer to the roots of the corn, which may be of great service to it in dry weather: and also when the barley has been up three weeks or a month, it may be a good method sometimes to roll it over with a weighty roller, which will again press the earth close to the roots of the corn, and thereby prevent the sun and air from penetrating the ground in dry seasons; and this rolling of it before it flakes, may likewise cause it to tiller out into a greater number of flakes; so that if the plants should be thin, it may cause them to spread fast so as to fill the ground, and likewise strengthen the stems.

If the corn should grow too rank, as is sometimes the case in a wet spring, mowing is then much better than feeling it, because the hay takes off only the rank tops, but the sheep feed upon all indifferently; nor should they even in any case be left upon it too long, because, being particularly fond of the sweet end of the flack next the root, they bite so closely as to injure the future growth of the plant.

Barley is ripe when the red ear, as the farmers term it (a reddish colour on the ear), is gone off, or when the ears droop and fall as it were double against the straw, and the flacks have lost their verdure. If it be full of weeds, it must lie in the swath till they are dry. It is not apt to shed, but in wet weather it will be apt to sproat or grow mufly; and, therefore, every fair day after rain it should be shook up and turned; and when it is tolerably dry, let it be made up into shocks: but be careful never to house it till thoroughly dry, left it may burn, which will make it malt worse than if it had spired in the field.

BARLEY.

Caulic Indian. See Verbasium Scordilla.

Barley Water (Decataum Hordei P. Lond. & Ed.) It is of some conquence that the preparations which generally fall under the care of the nurse, should be made with as much attention as those of the apothecary. Barley water, either by itself or with a variety of additions, forms an agreeable and valuable drink for the sick room. When prepared in the following manner, it is smooth, uniform, and palatable. Take of pearl-barley two ounces, water five pounds: first wash the barley from the mealy matter that adheres to it, with some cold water; then boil it a little with about half a pound of water to extract this colouring matter; throw this away, and put the barley thus purified into five pounds of boiling water, which is to be boiled down to one half, and strained.

Barley Water Compound. (Decataum Hordei Composition P. Lond.) Take of the preceding barley water two pints; sliced figs two ounces; liquorice root, sliced and bruised, half an ounce; raisins, itsone, two ounces; water one pint; boil to two pints, and strain. This decoction is more valuable than the former, and is very palatable; it forms a good demulcent liquor in fore throats of every kind, and is very considerably nourishing. It is apt, however, to cloy the stomach if taken in large quantity; lemon juice, or any other acid, may be added to it with advantage.

Barley-bird, in Ornithology, a name given in Suffolk to the Sifkin.

Barley-corn, is used to denote a long measure, containing in length the third part of an inch, and in breadth the eighth.

The French carpenters also use barley-corn, grain d'orge, as equivalent to the line or the twelfth part of an inch.

Barley-corn, grain d'orge, is also used, in building, for a line midway between the mouldings of joiners' work, lending to separate or keep them aliduer; thus called because made with a kind of plane of the same name.

Barley-sugar. See Sugar.

Barley-corn, in Geography, a creek on the south-west coast
coast of Ireland, between Mizen-head, the Notum of Pto-
keny, and Browhead in the county of Cork. N. lat. 51°
24'. W. long. 9° 40'.

BARLOWE, WILLIAM, in Biography, was a descen-
dant of the ancient family of the Barlowes in Wales, and born
in the county of Essex. He was at first a monk in the Augu-
dine monastery of St. Oith in Essex; and having
 commenced his education in this place he finished it at Ox-
ford, where he obtained the degree of doctor in divinity.
He afterwards became prior of the canons of his order at
Bisham in Berkshire, and at the dissolution of the monas-
tery he resigned his vows, and proceeded on many abbeys and
hospitals to follow his example. In 1525 he was appoint-
ed bishop of St. Asaph, and in 1576 translated to St. Da-
vil’s, where he formed the unsuccessful project of removing
the episcopal see to Caermarthen, as being situated more
in the centre of the diocese. He was a favourite of king Henry
VIII., and was employed by him in the matter of his di-
 vorce; and he was also much esteemed by lady Ann Boleyn.
In 1547, he was translated to Bath and Wells; but as he
was attached to the protestant religion, he was deprived of
his bishopric in 1553, upon queen Mary’s accession, on
pretence of his being married, and committed to the Fleet
prison. Having made his escape from confinement, he re-
tired with many others to Germany; where he remained in
a poor and disreputable condition till the happy inauguration
of queen Elizabeth. On this occasion he returned to his
native country, and in 1559, was promoted to the see of Chi-
chester, where he died in 1568. He was reckoned a learned
prelate; but appears, notwithstanding his profession of the
protestant religion, not to havepossessed the spirit of a mart-
try. Besides other pieces which he wrote, he was concern-
ed in the composition of the treatise entitled “The Godly and
Pious Institution of a Christian Man,” commonly called the
“Bishop’s Book,” printed at London in 1557; and in
the reign of Edward VI. he is said to have translated into Eng-
lish the “Apocrypha” as far as the book of Wisdom.
He had five daughters, all of whom were married to bishops.
Biog. Brit.

BARLOWE, WILLIAM, son of the former, was born in
Pembroke-shire, and in 1560 entered at Bath college. He
afterwards travelled, and became skilful in navigation.
On his return he took orders in 1575, and obtained several
premiers in the church, the last of which was that of the
archdeaconry of Salisbury, to which he was promoted in
1614. He died at Eafon near Winchelsea in 1625. In
his acquaintance with the nature and properties of the loam-
stone, he seems to have preceded Dr. William Gilbert, and
wrote upon this subject twenty years before Gilbert’s book
was published. He was the first that made the inclinatory
instruments transparent, and to be used hanging with a glass
on both sides and a ring at the top; and he also contrived
to hang it in a compass box, and to adapt it for use at
sea. He was also the first person that discovered the
difference between iron and steel, and their respective tem-
peratures, for magnetical purposes. He also shewed the right
method of touching magnetic needles, and shewed how to
piece and cement lead-plates. Moreover he explained the
reason why a lead-plate being double caked, takes up so
great a weight. In these subjects he wrote the
Lond. 1597; “Magnetic Advertisements, &c.” 4to.
Lond. 1616; and “An Answer to Dr. Ridley’s Animad-
versions on this work.” Biog. Brit.

BARLOW, THOMAS, a learned English bishop of the
17th century, was born at Langhill in the parish of
Orton in Wiltshire in 1607, and educated at Queen’s
college in Oxford. In 1635, he was appointed reader of
metaphysics in the university, and his lectures were pub-
lished. On the surrender of Oxford to the parliament in
1646, he retained his fellowship, and in 1652 was appointed
keeper of the Bodleian Library. In 1657, he was chosen
provost of his college. Upon the restoriation he contrived
to be chosen one of the commissioners for restoring the
members that had been wrongfully ejected in 1648, and
in 1660 was created doctor of divinity and Margaret pro-
fessor in that department. In this year he wrote “The
Cafe of a Toleration in Matters of Religion,” which he
extended farther than any delines of that age. As he
was distinguished for his zeal in the civil and canon law,
he was often applied to as a counsel; and in 1671, he wrote
Mr. “Cottington’s Cafe of Divorce.” In 1675, he was
promoted, notwithstanding the opposition of archbishop
Sheldon, to the bishopric of Lincoln; and after his ad-
vancement wrote several pieces particularly against popery,
which served to found the alarm with respect to the danger
of a popish successor. However on the accession of James
II., he was one of the most forward in procuring thanks to
the king for his declaration in favour of liberty of con-
science, and he vindicated the regal power of dispensing
with penal laws; which conduct some have confused as ma-
nifecting an unwarrantable accommodation to the times,
and others have ascribed to his love of toleration. With the
revolution he adopted its principles, and avowed his allegiance
to the succession of James. As to his sentiments, he was in
theology a rigid Calvinist; and in philosophy a strict Arif-
totelian, and an enemy to the new mode of experiment en-
couraged by the Royal Society. As a bishop he neglected
his duties in his cathedral and diocese, and refuted con-
stantly at his manor seat at Bugden; nevertheless his tolerating
spirit and opposition to popery seem to have produced in
the author of the “Confessional” a singular predilection in
his favour. He died at Bugden in 1691, in the 85th year
of his age; and he was eminently distinguished by his learn-
ing and liberality. The works of this bishop, printed after
his death, were a volume of “Cafes of Confidences,” re-
 solved by him, 8vo. 1692; and his “Genuine Remains,”

BARLOW, FRANCIS, a painter of birds, beasts, and fish,
was born in Lincolnshire, and excelled in drawing every spoc-
cies of animals with great correctness; but his knowledge of
colouring was very imperfect. This artist died in 1702.
Pilkington.

BARM, otherwise called yeast; the head or workings
producing by the fermentation of ale or beer. It is
the froth that forms on the surface of beer or wine of
grains during their fermentation; which, mixing with
dough, raises it more quickly and better than leaven, and
makes the lightest bread. See Leaven, and Yeast.

BARMACH, in Geography, a lofty mountain of Peria,
in the province of Schirvan near the Caspian sea.

BARMANCOTTY, a town of Afi, in the country of
Thibet, five miles south of Sirinagur, and thirteen north of
Deuprag.

BARMEA Haven, is a large bay, situated about four
miles S.W. by W. from Cape Machicaco, two leagues N.E.
by N. from Placentia, and four from Bilboa.

BARMEN, a town of Germany, in the circle of West-
phalia and duchy of Berg, situate in a fertile valley to
which it gives name, five miles north of Laump.

BAR-MINE denotes such mine or orejas is adjudged
at a court of bargemote.

BARMOUTH, in Geography, is a small watering place
in the parish of Llanaber, Merionethshire, North Wales. The
houses
houses are singularly placed at the bottom and on the side of a steep hill which overlooks a narrow winding valley to the south, and the bay with St. George's channel on the west. The situation of the houses affords matter of adornment to most travellers; some being placed on the sands close to the beach, and others at such varied heights on the rocks, that in some of the winding paths a person may look into the door of one house on his right hand, and down the chimney of another on his left. This place is at the mouth of the river Mawddach, which at high tide forms a bay of about one mile over; but the entrance is rather unsafe on account of the sand banks. The Welsh call it Aber-maw, i.e. the mouth or confluence of the river Maw. Barmouth is much frequented as a convenient bathing place during the summer by many genteel families. There are a few bathing machines for the use of ladies, but the gentlemen commonly bathe from the boat. This place is the port of Merionethshire, and great quantities of flannel and hogs are annually exported hence. Mr. Pennant states that forty thousand pounds' worth of the former and ten thousand pounds' worth of the latter have been shipped from this port in one year. About one hundred vessels belong to this place, some of which fall up the river nearly to Dolgelly.

Not far from Barmouth, the river Mawddach divides into two arms, and forms a small island called Yays y Bradau, or the Friar's island. The number of houses in this parish is 317, and its inhabitants amount to 1463. Bingley's Tour round North Wales.

BARN, in Rural Economy, a covered building constructed for the purpose of laying up and preserving all sorts of grain, hay, straw, &c. Arable as well as hay farms should in general be provided with barns proportioned to the quantity of grain or hay they produce; though since the practice of flacking hay and grain and of threshing by mills has become more general, there seems to be much less need of large barns.

Buildings of this sort should have a dry, rather elevated situation; and be placed on the north or north-east side of the farm yard, but not by any means contiguous to the house or such offices as are connected with it.

Barns may either be constructed on wooden frames and covered with the outgates with weather-board, or built of brick or stone; which ever the country affords in the greatest plenty; but in either case, there should be such vent-holes or openings in their sides or walls as may be sufficient to afford free admission to the air, in order to prevent the mouldiness that would otherwise from the leat damp lodge in the grain. The gable ends of such buildings are probably always best be built up of brick or stone, on account of their greater solidity; the whole may be roofed with either thatch or tiles as can be most conveniently procured. They should have two large folding doors facing each other, on each side of the building, for the convenience of carrying in or out a cart or waggon load of corn in heaps or any other sort of bulky produce; and these doors should be of the same breadth with the thinner floor, to afford the more light and air; the former for the thrasher, and the latter for the purpose of winnowing the grain. Over the thinner floor, and a little above the reach of the flail, poles are often laid across from one beam to another, to form a kind of upper floor, upon which the thrasher may throw the straw or halm, to make an immediate clearing till he has time to follow it properly elsewhere; and on the outside over the great doors, it is sometimes convenient to have a large pent house, made to project sufficiently to cover a load of corn or hay, in case a sudden storm should come on before it can be hauled, and also to shelter the poultry in the farm yard from too great heat or bad weather of any kind.

It was formerly much the custom in countries that abounded in corn to have separate barns for wheat, for forring-corn, such as barley and oats, and for peas, tares, clover, sainfoins, &c. but where the grain, hay, and other similar produce can be thacked, the heavy expense of so many buildings of this kind may be avoided, and at the same time the different articles be preserved with equal safety and convenience. In the corn barns it was formerly also much the custom to have hay or large separate chambers formed in their sides or ends for the purpose of containing the grain when threshed out, straw, and other articles; but these at present are not so much in use. The hay barns should commonly be constructed of wood and not made too close. They are sometimes formed in such a manner as to be capable of being moved to different places by having low wheels or rollers fixed on the bottom frame. In grazing farms that do not afford a supply of straw for thatching the flacks with, movable roofs erected on strong upright polls of wood, or what are sometimes termed Dutch barns may be useful; as they may be raised or lowered at pleasure by screws or levers so as to accommodate themselves to the quantity of hay, either in proportion to the crop or its consumptions; while at the same time they are cheaper, more airy, and less troublesome in cases of heating, than close barns.

It is observed in the sixteenth volume of the Annals of Agriculture, in speaking of the construction of barns, that the underpinning should be of brick or stone, two feet high above ground, and the sides boarded; the roof of the barn is best covered with reed or straw, and thole of the flaches on its sides with slate or glazed tile; because they must be more flat, and the water which runs from the roof of the barn would injure most other coverings. At each end of the barn, and over the back door, small doors four feet square should be fixed at the height of twelve feet from the ground; the two former for putting corn in at the ends, and the latter for filling the middle of the barn after the hays are full. All the hays should have a floor of clay or marls, and the threshing floor be made with hard bricks, which will be sufficient for all sorts of grain except wheat and rye; and for threshing them it will be good economy to have planks of oak or red bricks fitted together and numbered, to be laid down occasionally and confined by a frame at their ends. A barn built on such a plan would hold a great deal of corn and be filled most conveniently; and if the flacks of corn were built at each end, they might be taken in without any carting. If more buildings are requisite, two may be added on the back side like the flatches in front; otherwise if doors are made under the eaves on the back side, as directed at the ends, and flacks be placed opposite to them just far enough to avoid the eaves dropping, by placing a waggon between them and the barn by way of a stage, these flacks may be taken in without carting; which method spares a great waste of corn and much trouble. The eaves of the roofs of the flatches rest upon the upper eills of the sides of the barn, and the outside wall of the flatches is eight feet high; the barn supplying the highest eill and one end of each flack, and the flatches in return are butterscots to the barn and strengthen it greatly.

It is remarked by the author of the Agricultural Survey of the county of Somerset, that the practice lately introduced of placing barns on a declivity cannot be too much recommended, as a warm commodious range of stalls for cattle, covered by the same roof, is by that means obtained.
Besides, the barn-floor, by being thus elevated, is rendered more durable, and left subject to vermin; the grain is kept more dry and sweet than on a ground floor, and cannot slip through it without discovery. The plan is indeed, in his opinion, also of unquestionable. Barns, when built in this way, should have a fourteen-sided, the arches of the eath falling in that way. Mr. Marshall, in the "Rural Economy of Yorkshire," also speaks highly of the advantages of barns formed in this manner.

In respect to the size of barns, the same writer has observed, that in Gloucestershire fifty-two by twenty feet in the clear, and from sixteen to twenty feet in height to the plate, is considered a good barn; these dimensions admitting of four bay of ten feet each, with a floor in the middle.

The advantage of having buildings of this sort conveniently situated, is extremely great both in regard to the feeding of cattle, sheep, and hogs, and likewise in the economy of labour, and the preventing of waste in different kinds of fodder.

The invention of thrashing machines has, in some measure, altered the construction of barns, as where they are made use of there should be contrived chiefly with a view to the distribution of the straw; the machines being built in the centre, with the grain flacks adjoining them, in such a manner as that they may be supplied without the annoyance of carts or horses. The barns in these cases need not be so large, but they should have granaries provided in them, which may probably be most conveniently placed over the floors. In most old barns, thrashing machines may be erected without much inconvenience or trouble.

But, notwithstanding the superiority of flacking grain in the open air has been fully shewn by different writers, and of course the necessity of large barns in a great measure obviated, there are still many agriculturists attached to the method of housing corn in the straw; it may therefore be proper to give a few plans and descriptions of such as appear to be the best calculated for that purpose.

At fig. 1, Plate I. of Agriculture, are given the elevation and ground plan of a small common barn used in most parts of the kingdom for the smaller kinds of farms. The thrashing-floor is in the middle; on one side of which acroft wall is sometimes raised to the height of about three feet, in order to keep the thrashed corn from being mixed with that which is unthrashed; is a space for containing the thrashed grain till it be cleaned, or a large quantity be accumulated for that purpose. It is about three feet in height, being covered over with boards, and only open on the side next the thrashing-floor of the barn.

At fig. 2, the elevation and ground plan of a double barn with two thrashing floors are given. In this fort of barn a wall is sometimes raised across the middle. These barns are often built of large dimensions, but possess few conveniences, except for piling up the grain while in the straw.

At fig. 3, the elevation and ground plan of an improved barn are given, in the middle of which is the thrashing floor, and on one side near the end a place for deposing the thrashed corn, with flails up to a small granary, below which is a place for putting potatoes, &c.; and on the other a division that may be made use of for different purposes, such as the rearing of calves, preferring implements, &c.

And at fig. 4, the elevation and ground plan of an open improved barn are shewn, the thrashing floor of which is placed towards one end. And on each side of it below are divisions for a great variety of different purposes; the corn being kept above in the straw till thrashed out. In this barn much expense is saved in masonry by the great number and largeness of the openings in the upper part, and at the same time the air is admitted more freely.

Fig. 5, is the representation of a Dutch movable barn which has many conveniences, and at the same time is capable of being made to cover the parts of such hay flacks as are cutting. It moves on fixed wheels each two feet in diameter, and costs, when complete, about sixty pounds.

Some degree of art, which must be the result of practice, is necessary in placing and piling up the theses in barns; and it may not be useless to observe, that it is always necessary to press them as close to the walls of the barn as possible, to be able to afford the largest room for rats or other vermin to creep in between them, for if they once get admittance, they will soon penetrate farther, lodge themselves in the mow, and do prodigious damage to the grain. Where this misfortune happens, the only remedy is to take down the mow, destroy the vermin, and pile it up anew in a more careful manner.

As the introduction of thrashing machines has made considerable alteration in the construction of barns, it may not be improper to give a few plans or representations by which the manner of their attachment to them may be rendered more clear and comprehensible. These machines may be wrought by different powers, as water, wind, or animals; but the first, when it can be obtained, is by much the best and most regular.

At fig. 1, Plate II. of Agriculture, are given a front and end elevation, with the plan, of a small barn adapted for a two-horse thrashing machine. The barn is only fifty feet in length within the walls, and fifteen in width. The walls are ten feet in height, which admits of a granary, or room thirty feet long above the machine, as is shewn by the dotted line in the elevation, which denotes the extent of the granary as well as the height of the floor from the ground. The floor is not continued the whole length, in order that there may be more room left in the other end for containing the unthrashed grain, which is introduced at a, fig. 2, and 3. At e, fig. 2, is seen the space occupied by the machine within the barn, which is only ten feet by fourteen, including the distance from the wall; c, d, fig. 2 and 3, shew the horse beam or lever; which is twenty four feet in length, and which gives motion by a laying shaft through the wall, to the machine within. In this there is no fixed or cover over the horse path and parts of the outside of the barn, as is usual, except g, h, fig. 2, which is closely boarded to protect the wheels of the first movement from the effects of weather, a part of one side being fixed with hinges for the purpose of opening to apply grease. The expense of a machine on this plan will be from thirty to forty pounds, according to the strength and manner of its being put together.

And at fig. 4, are seen the front and end elevations, with the plan, of a barn and horse thrashing machine upon a much larger scale, being intended for three or four horses or other forts of cattle; and designed to winnow or clear the grain at the same time that it is thrashed out. It may likewise be contrived as to be built up to the granary above, to split beans, cut straw, and perform several other operations, such as churning, pumping, grinding, &c. Such a barn and machine will suit a farm of almost any extent. The fixed over the horse-path and first movements is mostly made with a conical roof merely for the purpose of covering them; but as the expense is considerable, it is here made to answer other uses. It is square, as shewn at fig. 5, by a, b, c, d; the dotted circle is the horse-path, in the corner of which stands the upright axle e, fig. 6. Above this, by raising the pillars to a proper height, may be obtained a convenient place.
place either for putting corn in the straw till threshed out, or for keeping straw or hay, or as a granary. But in either case the floor must be so constructed as to support the weight upon it without sinking in the middle. A communication with the barn may be made near the threshing machine at $j$, $k$, which will afford an easy access to the machine in case grain be deposited there to be threshed. In this barn, the machine is erected on a floor raised seven or eight feet above the ground-floor, in order that there may be sufficient room for the farmer or windowing machine below. This floor may be extended the whole breadth of the barn and fifteen feet or more towards $i$, from the back part of the machine at $j$, by which, and being properly partitioned below, a very necessary and useful division $f g h i$, will be obtained for containing the grain till hoisted up to the granary. The doors of this place may be locked by the farmer, if thought necessary, during the time of threshing. The space $k$ will contain the chaff blown by the farmers. There is a door through at $g$ to render the communication more easy and expeditious from the part $i$, where the unthreshed grain is deposited; as it may be proper to look often while the machine is at work: there likewise be a door in the partition at $h$; but this is not so very necessary, as the farmer can easily see what his servants are about at $m$, where the straw goes, by looking on the threshing-floor, to which there should be steps up at $n$. This machine may also be so constructed as to raise away the straw, and throw it down to $m$; which leaves the labour of a perfect in raking from the machine.

The expense of a machine on this plan, when made to clean the grain and raise away the straw only, will amount to about sixty pounds exclusive of flooring, &c.; and when made so as to hoist up the grain, split pease or beans, and cut straw, from six to ten pounds in addition for each.

Other more powerful machines of this kind will be described under the article Threshing Machine.

BARN FLOOR, in Rural Economy, the space or floor on which the grain is threshed out by the flail. It is for the most part made in the middle of the barn, and should be so formed as to be perfectly close, firm, and strong. It is sometimes termed threshing-floor. In constructing these floors, various sorts of materials are employed; such as compositions of earthy kinds, fluxes, brick, and wood. The last, when properly laid and put together, is probably the best and most secure from such causes as are liable to injure grain. The floors of barns, when made of wood, are sometimes so contrived as to be moveable at pleasure, which is a great convenience in many cases. Barn floors are made of different dimensions, but from twelve to fourteen by eighteen or twenty feet may be considered as good sizes.

As the floor or threshing-place, is the principal part of every barn, the greatest care ought to be taken in making it. In order to this, in some places the surface of the intended threshing-place is dug away to the depth of about six inches; and the earth thus taken out, when of a proper kind, after being well cleared of stones, is mixed with the strongest clay that can be procured, and with the dung of cattle. This mixture is then worked together with water till it is of the consistence of stiff mortar, and the compost thus made is spread as smooth and even as possible with a trovel upon the spot from whence the earth was taken. As it cracks in drying, it must frequently be beaten down with great force, or rolled with a heavy roller, until all the crevices are filled up; and this must be continued till it is quite solid, hard, and firm. Earthen floors are not however to be recommended, except where the materials are extremely good, and the method of forming them well understood, which is but seldom the case.

The best barn floor, both for threshing upon, and for keeping corn, is that which is the driest, smoothest, most completely solid, and consequently the most free from cracks and holes in which insects and vermin may shelter themselves and breed. The ancients were remarkably careful in this last respect, as is evident from the writings of Cato, Varro, and Columella. The loft of these relates particularly the great pains they took, first to dig up the ground to some depth, in order to moisten it with fresh loops of oil, but not with any that had saline matters in them; then to mix it thoroughly with chaff, and ram it down as close as possible; afterwards, as it dried, to flop all the cracks and crevices that appeared; to continue heating it down with great force to render it quite level; and, lastly, to strew it again with chaff, which they trod in, and then left it to be completely dried by the sun. All of them agree, that the lees of oil thus used prevent the growth of weeds in the floors, and contribute to preserve the corn from being plundered by the mice and ants. In this they were, however, probably mistaken. Their barns were always heated high, and as dry as possible. A floor made in the above manner, though not good, was probably preferable to either stone or the earthen floors formerly common in many parts of this country, from which such granaries have been communicated to the corn, as has rendered wheat, for example, slippery or a flailing bushel worse either for keeping or exporting. Bricks, when hard and well laid, may form a tolerable floor for many purposes; but, from their attracting moisture, are not by any means to be recommended where grain is to remain much upon them. And most parts of these are liable to the same objection.

Wood is by much the best for this use. Boarded threshing floors, made of sound, thick, well-seasoned planks of oak, are excellent for threshing upon, will last a long time, and may be converted into good floorings for rooms, by planing them down after they are become too uneven for the purpose originally intended.

There are various ways of laying and constructing barnfloors, when made of wood. The most common method is that of nailing the planks, after their edges have been true and well jointed, down to wooden sleepers firmly placed on the ground. But in the midland counties another method is followed, which, Mr. Marshall says, is that of first having the floors laid with bricks, and then covering them over with the planks, without any other confinement than that of their being dovetailed together, or ploughed and tongued and their ends let into the floor or walls placed in the usual manner on each side of the floors. The advantages of this method of making the floors are, that when the brick work is well executed and made perfectly level, vermin cannot be concealed underneath them, nor damp air be communicated; besides, floors formed in this way are found to wear better than those laid firmly upon sleepers. The planks employed in this way should, however, always be well seasoned. It is evident, notwithstanding, that where barn floors can be made hollow, they must be much better for the purpose of threshing upon than such as are either placed on brick work or the ground, from their greater elasticity; the grain is of course threshed out with more ease and certainty. But in whatever manner these floors are constructed, they become expensive, and do not last any great length of time. Such as are laid on the common ground, upon three fells, with two-inch oak planks, will in general cost from eighteen to twenty pounds; and only last fifteen or twenty years; and such as are made hollow, and placed wholly on brick work,
or only on brick quoins, with two-inch and half oak planks, are still considerably higher, being often from twenty-five to thirty-five pounds or more, and not much more durable. Beech floors, which were lately introduced instead of oak, have been found not to last more than seven or eight years; consequently to be by no means advantageous.

In order therefore to obviate the continued heavy expenses of these floors, as well as the great consumption of timber in the construction of them, and also to guard against the great waste of grain in threshing upon them after they begin to decay, another kind of barn floor has been invented by Mr. Upton of Petworth in Sussex, which has been found on trial to prevent these inconveniences in a great measure, and at the same time to afford other great advantages, such as those of being more easily drawn upon by loaded waggons or carts; providing, when down, comfortable shelter for hogs; and, when turned up, being capable of being employed as a stable, ox-stall, hovel, or cart-house. This is the moveable barn floor, which, it is said, can be placed or displaced in a few minutes by two persons.

This new-constructed hollow floor, is composed of oak planks five feet eight inches in length, and one inch and an half in thickness, and cools from twenty-three to twenty-four pounds, by these dimensions being considerably less than those used in common barn floors, much advantage is gained in respect to timber. besides, planks of deal, beech, or elm, may be made use of, as they will not be liable to decay from there being little or no dampness, and in this way the expense be lessened; and when timber from the estate is employed, it may be still further diminished; as these floors may be composed of stuff of small scantlings, which may be had from short timbers of but little value in comparison to those made use of in other kinds of barn floors. It is supposed that floors constructed in this method will last an hundred years, or as long as the barns; as they are perfectly free from damp from their being so much raised from the ground when down; also from their being movable; when there are more barns than one in the same yard, they may be conveyed from one to another, and by that means save the expense of having different floors.

At fig. 7. Plate II. of Agriculture, may be seen the representation of a barn floor of this kind; one part of which affords a view of the floor as laid down for threshing upon, and the other part is raised up, with racks for feeding cattle, &c. a rack boards, b slip boards for admitting air, c wood floor, floor for the slip boards d to rest upon, e movable floor, to one part of which are wooden legs serving to support it when it is necessary to put the displaced timbers into the receive; f a receive for receiving the threshold grain before it is winnowed or for containing the moveable timbers; g an iron hook to lift the floor up with when not used for threshing upon; there are two of these hooks employed in the barn; h the moveable timbers that support the floor, having grooves along their surfaces to prevent the loss of grain; two of these timbers are represented larger at i; one being the cross piece with a leg and tenon for fixing in the floor mortises, the other intended to lie lastly, and level with the floor of the barn; in the ground are fixed stones with mortises in them to receive the tenons of the timbers described above; j the ground, which should be made of materials sufficiently hard to prevent the horces, carts, or waggons from making depressions in it; k pegs with iron halps, to support the floors when out of use, l racks for feeding cattle at, when the barn is applied to other purposes than threshing upon. When the floor is not wanted for threshing upon, the floors may be first turned up and fixed with the iron pins, bolts, and halps; then the middle timbers are taken out and placed on the ground, on the side opposite to the receive where they were to be deposited when out of employ; afterwards that part of the floor which has legs to support must be let down, putting the timbers into the receive, and turning the floor up again.

Though floors of this kind may be highly convenient and useful in particular instances of large barns, where much threshing by the flail is required, yet from their complexity, and their requiring much room when out of use as floors, they do not seem well calculated for those of the smaller kinds.

• Barn, or White Owl, in Ornithology, is in England the common name of that species of Strix, which is found about barns and out-houses, and which is specifically called flammeus by Gmelin, and some other naturalists.

BARNABAS, Saint, in Biography, a teacher of Christianity contemporary with the apostles, was a Levite of the country of Cyprus. His original name seems to have been "Joseph," and the appellation of "Barnabas," signifying "Son of Consolation or of Exhortation," was conferred upon him by the apostles. He was one of those Christians who, soon after the resurrection of Christ, sold their property and laid the money at the apostles' feet. Acts, iv. 36, 37. By him St. Paul was prefented to the other apostles three years after his conversion, or about the year 37 of the vulgar era; and he was appointed a missionary to Antioch, in order to confirm the disciples. From thence he went to meet Paul at Tarus, and they reposed together a year at Antioch; and were afterwards entrusted with the conveyance of alms to the Christian brethren at Jerusalem. A. D. 45. Here he declared joint apostle of the Gentiles with Paul, whom he accompanied to various places and with whom he co-operated in preaching the gospel. At length a division occurring between them with respect to Mark, whom Paul refused to accept as a companion; they separated, probably in friendship and mutual good will; and Barnabas with Mark as his associate went to Cyprus. St. Luke bears this honourable testimony to Barnabas, that he "was a good man, and full of the Holy Ghost, and of faith." Such is the substance of the account given of him in the New Testament. Some of the ancients, however, have supposed that he was one of Christ's seventy disciples, whom he employed during his ministry as a preacher in the land of Judaea. It has been said that he suffered martyrdom, being stoned to death by the Jews of Cyprus at Salamis; that he was buried by Mark in a cave near that city; and that his body was discovered in this island in the reign of the emperor Zeno about A. D. 488, with the gospel of St. Matthew written in Greek with his own hand, upon his breast. Lardner's works, vol. ii. p. 11, &c.

BARNABAS, Epistle of, in Ecclesiastical History, an epistle full extant, ascribed to St. Barnabas. It consists of two parts; the first being an exhortation to constancy in the belief and profession of the Christian doctrine, particularly as to its simplicity without the rites of the Jewish law, and the second part containing moral instructions. Learned men have differed with regard to the genuineness of this epistle. It is cited by St. Clement of Alexandria and by Origen. Eusebius reckons it among those books that are fruitful, meaning probably by the term, contradictory. St. Jerome says, that it was read for edification among the apocryphal Scriptures. Amongst the moderns, Pearson, Cave, Du Pin, Wake, Dr. Clarke, and many other learned men, suppose it to be a genuine epistle of Barnabas the companion of Paul. Some are doubtful, as Cotelierus, who inclines to think that it was not written by Barnabas. The objections against the genuineness of it are strongly urged by Balnage.
Bapore, and also by Mr. Jeremiah Jones. To this purpose he alleges that it is not in any of the ancient catalogues of sacred books; that it is not cited in scripture by any of the fathers; that it was not read in the assemblies of the primitive Christians; that it contains contradictions, notorious falsehoods, and grofs mistakes; and also many things that are trifling and silly.

Motheim says that it was the production of some superstitious Jew, whose attachment to Jewish fables, as well as mean abilities, shew that, notwithstanding the uprightness of his intentions, he must have been a very different person from the true Barnabas who was St. Paul's companion. Mr. Jones supposes that it was written by a peron who had been originally a Gentile or Pagan.

Dr. Lardner thinks it most probable, that it was written by Barnabas, soon after the destruction of Jerusalem by Titus, in the year of our Lord 71 or 72; and that it was addressed not to Jews, as archbishop Wake supposes, but to Gentiles, or perhaps rather to Christians in general, and intended to abate their respect for the peculiar rites and institutions of the Jewish laws and to shew that they were not binding upon Christians. It was written in Greek; but the first five chapters or sections, and a part of the fifth, are wanting in the Greek copies. It is however entire in an ancient Latin version. This epistle has no inscription, as it is not directed to the Christians of any particular place; and on this account it has been sometimes called a Catholic epistle. Lardner's works, vol. ii. 12, &c. Jones's New and Full Method of settling the Canonical Authority of the New Testament, vol. ii. p. 509, &c. Motheim's Eccle.

Hist. vol. i. p. 113.

Barnabas, St., Gospel of, a furious gospel mentioned by pope Celestus, in his decree against apocryphal books. The Turks have a gospel under this name, in which there are many things injurious to Christ and honourable to Mahomet. It was composed in Arabic, as M. de la Croze thinks, under the emperor Frederic II., A.D. 1211 to 1245, and was translated into Italian about the middle of the 15th century. Professor White has given extracts from this gospel at the end of his "Sermons at the Bampton Lectures."

Barnabas's St., Day, in the Calendar, a Christian festival celebrated on the 11th of June.

Barnabas, Cape, in Geography, lies in the north-west of America, in N. lat. 57° 13', between Trinity island and Cape Greville.

Barnabas, St., Island, is situated at the mouth of a small river of this name which falls into the river St. Lawrence, and is remote to the north-east on the southern or backshore more in coming down from Quebec.

Barnabites, in Ecclesiastical History, an order of religious thus called from the church of St. Barnabas at Milan, where they were first established, and which was bestowed upon them in the year 1545; and not as some have imagined because St. Barnabas was their patron; in reality, St. Paul is the patron of the Barnabites. The Barnabites are regular priests of the congregation of St. Paul. Their habit is black, and the same with what they wore when first established, in 1535, by the express bulls of pope Clement VII. and afterwards confirmed by Paul III. Their office is to instruct, catechize, and serve in mission.

Barnaca, in Geography, a small island near the west coast of Ireland, situate in Black Sound Bay.

Barnacles, in Ancient Geography, a town of Hispamia Tarraconensis, in the territory of the Carpathians. Ptolemy.

Barnacle, or Barnacle, in Conchology, is the common name of the species of Lepas called Anatifera; and is applied also in a general manner to all the shells which belong to the Lepas genus.

Barnacle-Goose, of Bernacle-Goose, in Ornithology, the common English name of that kind of goose which was deemed the offspring of the Lepas Anatifera in the sixteenth century. See Anatifera, and Anas Erythrophus, the latter being the Linnaean name of the Barnacle goose.

Gen. Ch. Col. common, somewhat ventricose, spreading at the tip, imbricate; scales numerous, gradually longer from the base to the tip; the inferior or exterior, ovate, close imbricate, sharp, pungent; the superior or interior, subulate, flat, spreading, pungent. Cor. compound, rayed; corollae hermaphrodite, tubular, very few (three or four), remote, in the disk ligulate, in a simple series, in the ray. Proper to the former, funnel-form; tube very short; border hairy, five-parted; parts converging. Proper to the latter, ligulate, lancolate, spreading at the base, incurved at the tip, and split, outwardly very hairy; tube longer than the calyx. Stam. filaments five; stamens cylindric, tubular.

Pfl. germ ovate; style filiform, longer than the stamens; stigma bihidi; stigmas spreading, ovate-rounded. Per. none; calyx converging; feeds very many, ovate, hairy; hairs reversed. Down of the flowers of the disk brantly; rays fimbriate, fluff, broken backwards, naked or covered with minute hairs; of the radial flowers long, erect, spreading, many-rayed, feathery, flos. Recept. flat, villous, without chaff.

Eff. Gen. Ch. Col. naked, imbricate, pungent. Cor. radiate; down of the ray feathered, of the disk brilly, broken backwards.

Species. Barnadesia spinosa is a shrub with very smooth branches, set with a pair of thorns at their origin, which at first were flipples; they are petalous, brown, fimbria; leaves alternate, simple, ovate, entire, sharp, flat, veined, somewhat hairy on both sides, with small cushions; petals very short; flipples in pairs, small, fimbriate; flowers in panicules, terminating; calyx pubescent. The flower is singular in having two sets of down. This is the only species of this genus, is a native of South America, where it was discovered by Muttis.

Barnard, or Bernard, John, in Biography, was born at Calcot in Lincolnshire, and educated at Queen's college in the university of Cambridge. In 1634, he was admitted by order of the visitors appointed by parliament, fellow of Lincoln college at Oxford. After the restoration, he was confirmed, and was promoted to be prebendary in the church of Lincoln. He died at Newark, on a journey to the Spa, in 1683. He was in good repute for his learning and orthodoxy principles, and was author of the following books: viz. "Centum Clerior, against Scandalous Ministers," &c. 4to. 1663; "Theologico-Historicus, or the Life of Dr. Heylyn," whose daughter he married, 8to, 1683; "An Answer to Baxter's false accusation of Heylyn;" and a "Catechism" for the use of his parish. Biog. Brit.

Barnard, Sir John, a patriotic citizen and distinguished magistrate of London, was born at Reading in Berkshire, in 1685, of parents who were quakers, and educated at a school belonging to persons of this persuasion at Wandsworth in Surry. In early life he was distinguished by the integrity and candour of his mind, so that all differences among his school-fellows were submitted to his decision. In the intestant year of his age, his father, who was now settled
London in the wine trade, introduced him into his own business; and his conduct was such as fully to justify the confidence that was reposed in him. Among other occupations that occupied his thoughts and time, he directed his particular attention to religion; and without doubt from conviction, renounced the professions of his parents, and became a professed and private member of the established church. Accordingly he was baptised by Dr. Compton, bishop of London, after several previous conferences, at his chapel in Fulham, in 1703. It was the uniform practice of Mr. Barnard, from his earliest youth, to associate with persons of riper age than his own, and with such as were distinguished by their talents, learning, and religion; and his improvement in knowledge and virtue corresponded to the election he made of his companions and friends. In this course of religious application to mental culture as well as to secular employment, Mr. Barnard persevered till he had attained the thirty-sixth year of his age; and he was only known in private life by the excellencies of his character. About this time a bill that materially affected the wine trade had passed the commons, and was depending in the upper house. The merchants that were likely to be injured by the operation of this bill, appointed Mr. Barnard to state their objections before the lords; and such were the abilities which he manifested on this occasion, and such was the success that attended his exertions, that in 1721 he was proposed, without his knowledge, as a candidate to represent the city of London at the next election, which took place in the following year. The contest was as warm as any that had ever been known in the city; but Mr. Barnard, though he declined all personal solicitation, succeeded by the zeal and activity of his friends. His parliamentary conduct, during a period of forty years, was in the highest degree independent and respectable; and he derived from his character as well as talents singular influence. He distinguished himself by his opposition to the measures of administration, then conducted by Sir Robert Walpole, and particularly to the extenuation of the excise, which he condemned both in a commercial and political light, and which, by his vigorous and affiduous efforts, he induced the minister at length to abandon. Headlee of popularity in measures which in his judgment concerned the good of his country, he attempted to reduce the interest of the national debt from four to three per cent.; and by his endeavours incurred a temporary odium. In 1732 he had obtained the honour of knighthood, on occasion of presenting a congratulatory address to King George II.; and in 1737 he was raised to the dignity of the chief alderman of the city of London, and in thus supporting his character he executed with singular reputation to himself and advantage to the public. So attentive was he to the duties of this office, that he would not sleep a single night in his house at Clapham, lest any person should be injured by his temporary absence. No magistrate was ever more vigilant in his attention to the internal police of the city over which he presided; and blended lenity with severity in the administration of it with so much dexterity. He would never suffer any person to be committed to prison for a single night, till the accusation against him had been fairly heard; for he well knew the danger to which unguarded youth would be exposed even by a short abode in those receptacles of infancy. The state of our goals had been the object of his particular investigation, and he was fully apprized of those abuses that needed correction and restraint. In 1745 Sir John Barnard took the lead in signing an agreement to take bank notes in lieu of public credit at a period of peculiar danger. In 1749, he became the father of the city; and the London merchants had previously, in 1747, testified their regeneration of him by erecting his statue in the Royal Exchange. This token of respect, however, he disapproved; as he thought that no character was entitled to it, till its perseverance in integrity had been vexed by death: and such was his modesty, that he never after transacted business within this edifice. In 1754 he was for the last time, without solicitation and in opposition to his own wishes, elected a representative of the city; but his infirmities increasing, he thought proper, in 1758, to resign his alderman’s gown. After some years of honourable retirement, he died at Clapham in 1764, leaving one son (distinguished by his talent in the polite arts, and by his admirable collection of pictures) and two daughters. Few persons ever cultivated a character so uniformly respectable as Sir John Barnard. He was not only blameless, but eminently exemplary in the various relations and offices of life. To the faithful and active discharge of the personal and social duties, he added a most devout sense of religion. The first hour, at least, of every day was employed in the exercise of devotion and the study of the scriptures. He attended public worship twice on a Sunday, and was confiant in receiving the communion. He had such a high reverence for the bible, that he always expressed a great dislike of any attacks which were made upon its sacred original and authority. Although he re- habited the profession of his youth, he retained, in a considerable degree, that simplicity of manners and plainness of drefs which distinguished the respectable body to which his family belonged. But though he was modest in his deportment, he was firm and fearless in the discharge of his duty. His language was clear, concise, and unaffected; and his wisdom and knowledge were recognized by persons of the first character in his time; insomuch that he was urged in 1746, by King George the second, to accept the office of chancellor of the Exchequer, which he refused. Lord Granville and Mr. Pulteney frequently consulted him on affairs of moment; and lord Chatham, when Mr. Pitt, has been known to flile him the great commoner. The nure of Pope, by exhibiting him in contrast to worthless wealth and title, has immortalized his name.

"Barnard in spirit, sense, and truth abounds;
Pray then what wants he? Fourscore thousand pounds?"

Biog. Brit.

BARNARD, in Geography, a township of America, in Windor county and state of Vermont, containing 673 inhabitants. It gives rise to the northern branch of Water- quee river, and is distant 65 miles N.E. from Bennington.

BARNARD CASTLE, or CASTLE BERNARD, a town of Durham, in England, 246 miles N.N.W. from London, and 26 from Durham. The town is about a mile in length, and consists of several streets; the principal of which is upwards of forty yards in width, and is mostly filled with halfdoe modern buildings. The air of this part of the country is remarkably salubrious, the market is abundantly supplied, and the situation pollutes every advantage to render it pleasant. The woollen manufacture has declined of late from the great use of cotton goods; much business is done by the tanners; and the floating trade is particularly flourishing. This town is mentioned as existing soon after the conquest; though it was then probably but an insignificant place, as it derived its chief consequence as well as its name from the magnificent castle founded here by Bernard Baliol about the year 1176. This fortress is situated on the summit of a high rock, and the most southern part of the town, and was anciently of much importance; maintaining a number of officers, and being walled with high privileges.
Iges by its different possessor. We find the names of John Balliol father to the king of Scotland, the celebrated Guy Beauchamp earl of Warwick, and Richard duke of Gloucester afterwards Richard III., occurring among the proprietors of the castle. The latter founded a college for a dean, 12 secular preists, 10 clerks, and 6 choristers; but it is presumed that his intentions were in part frustrated by the subsequent trouble of his reign, as no traces of this foundation are now discernible. In the reign of Charles 1., this castle, after being several years in the possession of the crown, was purchased by an ancestor of the present earl of Darlington, and gives a title to his lordship's eldest son. In the year 1699, it was created a barony by king William III. The present remains cover about six acres of ground. The parts of chief strength hard on the brink of a steep rock about eighty perpendicular feet above the river Tees, and every way command a most beautiful prospect. Many fragments of the ruins have the arms of Richard the third, who is supposed to have considerably contributed to this building. Though we can readily ascertain from the above that this fortress must have been a place of great strength and extent, yet it is not possible to form any competent idea what it was in its original and perfect state. Leland in particular mentions parts of which there are left but the ruins remain. The environs of the town are remarkably beautiful; the vale of the Tees abounding with a great variety of picturesque, pastoral, and augial scenery. From the castle cliffs northward, the river is bordered by a hanging forest of oaks on one hand, and on the other by fine meadow land. The extended battlements, the circular tower and the most flatly parts mantled with ivy, the brown rocks fringed with bristly wood, the brighter yellow towers, and the dark and shaded battlements, are contrasted by the azure lake on whose surface they are reflected. Near the path on the margin of the river is a fine new bridge of one arch, lately erected by Saurey Morriss, Esq. of Kokeby Park. The number of houes in the town-ship is 312, and its inhabitants 2966. Hutchinson's History of Durham, vol. iv. 460.

BARNARDO ISLANDS, are five islands on the north coast of South America, laid down in modern charts off the north point of the entrance into Morroqullo bay. They lie S.S.W. from the harbour of Carthagena, in the direction of the coast. To the west of four from them is the gulf of Darien, which is the limit between North and South America. These islands form a large bay and harbour in N. lat. 6° 35', and W. long. 70° 20'. The outermost island is called St. George's, the innermost is St. Gi- bertus, and Goeree island lies between them. The river Chenu is the outlet of these islands. BARNASNE, mountains of Ireland, in the county of Kerry, 8 miles S. W. of Killarney.

BARNaul, a town of Siberia, on the west side of the Obi, 100 miles S.S.E. of Kolyvan. It is situated on the Obi, in the government of Kolyvan, famous for its silver and copper mines, which also produce gold. These mines are much more productive than those of Nerchinske; for the pits hitherto opened in the latter have not continued or fledly veins, are never powerful, and seldom terminate in large reefs, are always poorer as they proceed in depth, and change their contents at every fathom. The mines of Barnaul belong to the crown. About 48,000 boors earn their capitation tax in working at them, and above the miners and other workmen properly belonging to them. The quantity of gold produced at Barnaul and the Shlangenberge from 1743 to 1780, amounted to 686 poold, 16 pounds, 49 solidrks of pure gold. BARNEGAT INLET, called in some maps New Inlet, is the passage from the sea into Flat-bay found, on the south-eastern coast of New Jersey, 68 miles N.E. from cape May, N. lat. 39° 47' 30", W. long. 74° 13'.

BARNER, James, in Biography, born at Elbing, in Weil Prussia, in 1641, applied himself early to the study of chemistry, in which he made such progress, that in 1670 he was engaged to give lectures in that art at Padua. After residing some years in that university he went to Leipzic, where he practised medicine with success. Retiring at length to Elbing his native country, he died there in 1686. Barner left several works on the subject of chemistry, but that by which he is principally known is his "Chymia philosophica, cum doctrina salubre, medicamentis fine igne culinari parabilius!" published at Nuremberg 1689, three years after his death, a work rather curious than useful. Haller Bib. Med. Eloy Dict. Histol.

BARNERA, in Geography, a small island of Scotland, near the west coast of Lewis, separated from the main land by a strait, called Loch Barnera, about a mile in. N. lat. 56° 25', W. long. 7° 3'.

BARNES, Joshua, in Biography, an English divine and classical scholar, was born in London in 1654, and educated in grammar-learning at Chrift's hospital, where he was distinguished by his proficiency in Greek, and by some Latin and English poems. In 1671, he was admitted a scholar of Emanuel college in Cambridge; and in 1678, he was elected a fellow of the same college. In his numerous writings, which were critical, poetical, and historical, he displayed more industry and fancy than taste and judgment. His memory was singularly retentive, so that he could write and converse in the Greek tongue with great readiness; though Dr. Bentley facetiously remarked of him, that he understood as much Greek as a Greek cobbler. But if he excelled in tenaciousness of memory, he was notoriously deficient in solidity of judgment; and therefore some persons recommended this pan to be inferred upon his monument: "Joshua Barnes, Felicis Memorie, Judicium expectans."

The enthusiasm of his temper was manifested in various singularities of opinion and conduct. Believing that charity never fails in this life of obtaining due recompense, he has given his only cost to a common beggar; and he used to recite strange stories of some unexpected remuneration which he had derived from charities of this kind. Of his talents and learning, and particularly of his acquaintance with the Greek language, he was vain and boastful; and at the same time he was prone to deprecate and abuse others. Of his works the most respectable were his editions of the Greek classics; and those he dedicated, without much appropriate felection, to persons of high rank. In 1669, he was elected Greek professor of the university of Cambridge. In 1700, he married a widow with a handsome jointure, who is said to have made the full advances; and, with a view to her amusement, and in order to induce her to supply him with money towards defraying the expense of his edition of Homer, he wrote a copy of English verses, designed to prove that Solomon was the author of the poems under Homer's name. He died in 1712, and was buried at Hemingford in Huntingdonshire, where a curious monument was erected to him by his widow, with an inscription partly in Latin and partly in Greek Analectics. The following memorandum is annexed: "Mr. Barnes read a small English bible, that he usually carried about him, one hundred and twenty-one times over at leisure hours." Of his numerous publications, the principal are the following: "A Poetical Paraphrase on the History of Esther," intitled, "A Διαδοχος παραφρασην," or "The Courtier's Looking-glass, &c." The story is paraphrased in Greek.
Greek verse, with a Latin translation in the opposite page and Greek scholia; to which is added, "An Homeric Parody on the same Story," "The History of that most victorious monarch Edward III. &c.;" Camb. fol. 1688. This historical work, for which the author's talents seem to have been very ill adapted, abound in false inferences and tedious digressions; and in long and elaborate speeches, after the manner of Thucydides and other ancient historians, which seem to be the result of his own imagination; the whole displaying neither the judgment of a politician, nor the taste of a good writer. "Euripidesque extant omnia, &c." Camb. fol. 1694. Defends a correction of the text of Euripides, this edition contains a preliminary dissertation on the ancient Greek tragedy, and another on the life and writings of Euripides. "Anacreon Teius, &c." Camb. 1705. In this edition, the poems of Anacreon are corrected, and much enlarged by the addition of several whole pieces and fragments. The life of Anacreon is annexed; and in the Prolegomena, the author treats of the antiquity and invention of lyric poetry, and the peculiar character and metre of that poet. The dedication to the duke of Marlborough is followed by a Greek Anacreontic ode upon the victory at Blenheim. The editor has also subjoined the epigrams of the ancients and moderns upon Anacreon, and some odes of his own composition under the title of "Anacreon Christianus," "Homeri Hias et Odysseus, &c.," 2 vols. 4to, Camb. 1710. This edition is furnished with an exact Latin translation, with the ancient Greek scholia, many notes upon the text and scholia, and various readings; to which are subjoined the "Barrochomymachin," the "Hymns and Epigrams," the "Fragments," and "Two Indexes." This edition of Homer has been generally esteemed as correct and complete; though in the Acta Eruditorum for Jan. 1711, there are some objections against it, which have been ascribed to Dr. Bentley. Barnes's editions of the Greek classics have of late years been sinking into disrepute; and modern critics place little confidence in his judgment or criticism. He has been charged, in some of his various readings, by the learned Dr. Clarke, with audacity and unskillfulness.

As for his other works, both in prose and verse, it would be tedious to enumerate even their titles; and this is the less necessary, as they are now no more confuted to total oblivion. Biog. Brit. 2

BARNET, also High and Chipping Barnet, in Geography, a town of England, situated in the hundred of Cauho and county of Hertford, 11 miles north of London. It has a market on Mondays, which has existed since Henry II.; and here are also three fairs annually. At this town, which is a great thoroughfare, the north road divides for York and Liverpool. Being situated upon an eminence, the prospects are extensive and agreeable; but there are no public buildings worth notice, except the church and a grammar school. The latter was founded by queen Elizabeth, and afterwards endowed by alderman Owen of the Filonomers company of London, for the education of nine children gratis. There are likewise alms-houses for widows, founded by James Ravencroft Esq. and his wife, in 1672. At the twelfth mile stone beyond the town, is erected a pillar to commemorate a signal battle fought on that spot on Easter day, April 14, 1671, between the house of York headed by Edward IV., and that of Lancaster conducted by the flour lord of Warwick, who, with many of the nobility and nearly 10,000 men, were slain. This was a decisive victory for the Yorkists, as it firmly established Edward IV. on the throne; although in a subsequent battle at Tewkesbury, the queen of Henry VI. and her son were taken prisoners. Barnet is governed by a magistrate, high constable, and other officers; and a court leet is held at Easter. In the town are 225 houses, inhabited by 1258 persons. Salmon's History of Hertfordshire.

BARNET, a township of America, in Caledonia county, and state of Vermont, containing 477 inhabitants, and distant 112 miles N. E. from Bennington.

BARNEVELDT, John Holden, in Biography, a minister of Holland, unanimously disinherited by his abilities and patriotism, was born in 1527. In his early negotiations on behalf of the states general with France, England, and the neighbouring powers, he gave great satisfaction to those who employed him, and gained equal credit and esteem in the judgment of Henry IV., and queen Elizabeth. As grand pensionary of the states of Holland, he obtained extensive influence; and firmly attached to the liberty of his country, he observed the growing power of the house of Orange, directed by the warlike and aspiring prince Maurice, with jealousy and apprehension. Amidst the collision of different parties, he was regarded as the leader of the opposition to the measures of that prince. The authority of Maurice depended in a great measure, on the continuance of the war with Spain, and Barneveldt was very diligent of terminating it. By his zealous endeavours to effect this purpose under the mediation of the king of France, he incurred the violent odium of the adverse party. At length, however, he succeeded by obtaining, in 1669, a truce for 12 years; the first article of which recognized the independency of the united states. Soon after this event, the disputes between the Arminians and Calvinists, or Remonstrants and Contra-remonstrants, curiously agitated the Dutch provinces. Barneveldt, inclined to the former, and the advocate of toleration, exerted himself in procuring for the Arminians or Remonstrants that liberty of conscience to which they had an equitable claim. Prince Maurice placed himself at the head of the other party, which was the most numerous; and probably took pleasure in the opposition and calumny encountered by Barneveldt in his endeavours to promote the cause of religious freedom and moderation. At this time, notwithstanding the suspicions excited against Barneveldt, as if he wished to subject his country again to the yoke of Spain, he was essentially forcing it by negotiating with James I. the reformation of the terrors of Flushing, Nieuwpoort, and the Brille, which had been put into the hands of Elizabeth as security for the money which she had lent to the states. Barneveldt's successes in this negotiation added James to the number of his enemies.

The religious disputes, which had been appealed in the province of Holland by the influence of Barneveldt, prevail'd so much in the other provinces, that a national synod was assembled at Dordrecht in 1618 in order to bring them to a termination. To this synod the kings of England and France, and most of the Protestant states of Europe, sent deputies; and the Arminians, who did not comply with the citation to appear before this assembly, incurred a formal condemnation. On this occasion, Barneveldt, Grotius, and other Remonstrant chiefs of the anti-Orang party, were arrested and imprisoned in the castle of Leiden. Barneveldt, however, was the devoted victim. Many accusations were alleged against him, as the fomenter of the disturbances that had occurred at Utrecht, and as an enemy to the public liberty; and being tried by a court, composed chiefly of his enemies, and admitting inadequate proofs, he was capitally condemned. Prince Maurice, to whom application was made from various quarters in his favour, remained inexcusable; as he would only promise a pardon upon condition of his being solicited by the family of Barneveldt: but they refused to do an act, which would imply the guilt of their
their venerable chief. Barneveldt prepared for death, and without asking any favour for himself, merely solicited the protection of his children. On the morning of execution, Barneveldt proceeded to the scaffold with a serene countenance; but being somewhat disturbed on his arrival, he exclaimed, with uplifted eyes to heaven, “O God! what is man!” Having prayed with the minister who attended him, he rose from his knees with composure, declared his innocence to the spectators, and refused the executioner to perform his office. His head was struck off at a blow, in his 72d year, May 13th 1619. The popular hatred soon subsided; his memory was revered as that of the purest of patriots, and most respectable men, and his death left a stain on the character of prince Maurice, which all his great qualities and services were not sufficient to efface. The states of Holland, in the register of his death, added these words, which may serve as a testimony to his character: “He was a man of great conduct, industry, memory, and prudence; yes, singular in all. Let him who flanders, take heed he fall. God be mercifull to his soul! Amen.” Never (says the French ambassadour De Maurier) was there so wise and virtuous a man as M. de Barneveldt. He had a majestick presence, and spake much in few words, with a grave and suddain eloquence.” Barneveldt left two sons in considerable employments; who being deprived of them by prince Maurice, engaged in a conspiracy against his life. One was beheaded, and the other made his escape. When the mother of him, who was taken and condemned, fell at the feet of Maurice supplicating his life, the prince expressed his surprize that she who had refused to ask her husband’s pardon, should condescend to intercede on behalf of her son. “I did not ask pardon for my husband,” said the mother with a noble spirit, “because he was innocent. I ask it for my son, because he is guilty.” Mod. Un. Hist. Gen. Biog.

Barneveldt’s Islands, in Geography, are two small flat islands, close to each other, on the west side of Terra del Fuego, partly surrounded by rocks, and 24 leagues distant from the fruits of La Maire. S. lat. 55° 49’. W. long. 66° 78’. Barneveldt, a town of France, in the department of the Channel, and chief place of a canton in the district of Volognes, 54 leagues S.S.W. of Cherbourg. The place contains 850 and the canton 876 inhabitants; the territory includes 215,516 kilometres, and 19 communes.

Barnfield, in Ornithology, is an aquatic bird, of which Oviedo speaks in his “Hift. des Indes,” book 14, c. 2; but which it is impossible to ascertian from what that author has said of it.

Barnsley, in Geography, a small market town of England, in the west riding of Yorkshire, 15 miles from Doncaster, and 176 north-west from London. It is situated on the side of a hill, and about five furlongs in extent. The town, though well built of stone, is called Black Barnsley; probably from its smoky furnaces, or rather from the foot of the moors with which it is surrounded. The land is very productive in wheat and other grain, and coal is also exceedingly plentiful. The abundance of stone, timber, iron, stone, &c. and the cheap living necessary for population, render this place very appropriate for any kind of trade. At present its wine works are surpassed the best in the kingdom; and the wire is of two sorts; the hard, made into teeth for cotton and wool cards, the soft for flocking-frame needles. Precedes of a leffer kind are weaving of linen, in which 500 looms are employed, and a glass manufactury of black bottles. Barnsley has a well built church, which is a chapelry under Silkstone, a free grammar school, a mar-
BARNSTAPLE, the Mattachees or Mattacheet of the ancient Indians, is a port of entry and post town, and the chief town of Barnstable county in North America. It extends across the peninsula, and is washed by the sea on the north and south, having Sandwich and the district called Mashpee or Mashpee on the west; and is about 5 miles broad and 9 long; 67 miles S. E. from Boston. Sandy-neck on the north shore, running east almost the whole length of the town, forms the harbour, and embosoms a large body of salt-marsh. The harbour is about a mile wide and four long; and the tide rises in it from 8 to 14 feet. Its bar, running off N. E. from the neck several miles, prevents the entrance of large ships; but small vessels may pass any part of it at high water. There is another harbour on the south, called Lewis's bay. Its entrance is within Barnstable, and extends almost 2 miles into Yarmouth. This harbour is commodious and safe, and is completely land-locked. In Barnstable there are but 20 or 30 ponds. The land here produces about 25 bushels of Indian corn to an acre, and rye and other grain in proportion. Wheat and flax are cultivated; the latter with success. From 12 to 18,000 bushels of onions are raised for the supply of the neighbouring towns. The fishery, which is annually increasing, employs about 100 men. The people who are in number about 2610, are generally healthy; and many instances of longevity occur. Many of the farmers are occasionally feamens, and many mariners and masters of vessels, who sail from other parts, are furnished by this town. N. lat. 41° 43'.

BARNSTEAD, a township of America, in Strafford county, New Hampshire, containing 807 inhabitants; 32 miles N. W. of Portsmouth, and 10 E. by S. from Canterbury on Connecticut river.

BARNSTORF, or BERNDORF, a town of Germany, in the circle of Welfphalia, and county of Diepholz, 8 miles north of Diepholz.

BARNTRUP, a town of Germany, in the circle of Welfphalia, and county of Lippe, 4 miles N. E. of Blomberg.

BARNWELL, a village situated about half a mile north-east of Cambridge, in England, was formerly of great consequence from its ancient priory, which, at the dissolution, was valued at 351 l. 15 s. 4d. The village has suffered very much by fire. Barnwell has a fair kept in its neighbourhood, commencing annually on Midsummer-day, and continuing a fortnight. This fair derives its origin from a custom of the children in the neighbourhood assembling on Midsummer-eve at Barnwell's well. A number of pedlars resorted to the plot, and exposed their merchandise for sale, so early as the reign of Henry I.; the articles brought being mostly pottery, the festival obtained the appellation of Pot Fair. It appears, however, to have assumed its legal form in the reign of Henry III. by whom it is said to have been chartered and granted to the priory. The fair is still proclaimed on Midsummer-eve, and the field in which it is held, is called Midsummer Green. But Barnwell is most famous for the great affembledge of merchandise annually held in a large meadow, called Sturbridge Fair; the origin of which Dr. Stukely was induced to ascribe to his hero Carausius: it is however evident that King John granted the whole for the use and maintenance of an hospital for lepers, who had an ancient chapel here; and the chaplain claimed the dues, till Hen. VIII, in consideration of 1000 marks paid by the corporation of Cambridge, gave them the grant of the fair, which was confirmed by Elizabeth. The field in which it is held is about half a mile square, having the rivers Cam and Stour on its northern and eastern sides. The booths are built in regular order, each row being particularly named, as Ironmonger's row, Bookseller's row, &c.; the centre is called the Dodderly, and chiefly occupied by droppers, merchers, and wholesale dealers in cloth. Sturbridge Fair is solemnly proclaimed on the 15th of September, by the vice-chancellor, proctors, and other officers of the university; and afterwards by the mayor and aldermen. The fated time for its continuance is fourteen days. Dramatic exhibitions are forbidden within nine miles of the university, except during this fair, and the week preceding. This was formerly the greatest mart in England; but its bullocks declining, owing to the circulation of commerce throughout the country, its consequence is very much diminished. Beauties of England and Wales, vol. ii.

BAROACH, BROACH, or BARUM, the ancient Baryceas, in Geography, a town of Hindoostaan, in the country of Guzerat, lying in the route from Surat to Amedabad, and fested on the great river Nerbuddah, about 25 miles from its mouth. Broach has been, in different ages, a port common both to Nearchus, the capital of Guzerat, and Tagara, supposed to be the modern Dowlatabad. The former was eight journies, the latter ten, from Broach. It is situated about 217 British miles north from the Pithana of Arain, or the modern Patham; and all kinds of mercantile goods dis throughout the Deccan were annually brought to Tagara, and from thence conveyed on corts to Baroach or Barygara across the Balha-Gaut mountains. Broach is famous for its manufacture of very fine batis and other cottons; and the water of the river Nerbuddah is said to have a peculiar property for bleaching of cloth to a perfect white ness. Agates are likewise an article of trade at this place; which are brought from the mountains near Bangour, and are mostly dipped at Cambaya. The fortresses of Baroach is large and square, standing upon a hill, which is the only eminence for many miles, and might be made very strong. The Dutch factory was established here in 1617, but is in a low state. N. lat. 21° 45'. E. long. 72° 58'.

BARROCCIO, FREDERICK, in Biography, an eminent painter of history and portrait, was born at Urbino in 1528, and instructed in the principles of painting by Battista Venetiano, and in that of perspective by his uncle Bartolommeo Genga. Having availed himself of their instructions till his 20th
the year, he removed to Rome, and pursued his studies with such facility and success, that he became one of the most

graceful painters of his time. At Rome he was particularly

encouraged by the protection of cardinal della Rovere, and

by the commendation of Michael Angelo. On his return to

Urbino he gained great applause by several pictures, and

more especially by that of a St. Margaret, which induced

pope Pius IV. to invite him to Rome, and to employ him,
in conjunction with Federigo Zuccaro, in the decoration of

his palace of Belvedere. It has been said that his superior

merits excited the jealousy of his brother artists to such a
degree that they gave him poison at an entertainment.

Whether this be true or not, his health declined; and for

the recovery of it, he was under a necessity of returning to

his native air, and of interrupting his labours. However,

by the attention, his life was prolonged to the advanced age

of 84 years. His genius principally inclined him to the

painting of religious subjects: and his works evince that

it was his chief ambition to imitate Correggio in his colouring,

and Raphael in his manner of designing. It is easy to ob-

serve, that he endeavoured to re semble the former illustrious

artist in the sweetness of his tints, in the harmony of his

colouring, in the graceful airs of the heads, in the disposi-
tion of his draperies, and the forms of his Bambinos,

though he sometimes expressed the molecular parts of the

human body too strongly. He seldom painted any his-
torical figure without having either modelled it in wax, or

placed some of his disciples in such attitudes as he wished to

e xpress: his father was the model for the Madonnas, and

his child for his Bambinos. He is said to have employed

seven years in painting at Assisfe, the birth-place of St.

Francis, a picture called the "Pardon," in which the figure of

the saint kneeling, by the force of thade, seems to rise from

the canvas. The works of this master are numerous; the

principal of which are at Rome, in the Belvedere, and several

curches; at Urbino, Assisfe, Corotna, Anconne, and other

towns in Italy; in the gallery of Florence; the Escorial;

and the duke of Orleans's collection. Barocci engraved

four of his own pieces with peculiar spirit, and more than

thirty more have been published by different engravers.

Pilkinson and Strutt.

BAROCHNE, in Geography, a town of France, in

the department of the Orne, and chief place of a canton in

the district of Domfront, 4 miles S.E. of Domfront.

BAROCCO, in Logic, denotes the fourth mode of the

second figure of syllogisms.

A syllogism in baroco has the first proposition universal

and affirmative, but the second and third particular and

negative: and the middle term, the attribute or predicate in

the two antitheses:—For example:

" BA Every virtue is attended with discretion;"

" RO Some kinds of zeal are not attended with discretion;"

" CO Therefore some kinds of zeal are not virtues."

" BAR Nulius homo non est bipes;"

"" OC Non omne animal est bipes;"

" O Non omne animal est homo."

BAROLITE, in Mineralogy. See WITHITE.

BAROMETER, compound of baro, weight, and

metre, an instrument for measuring the weight of the

atmosphere and its variations, in order chiefly to determine

the changes of weather, and the height of mountains, &c.

The barometer is frequendy confounded with the baroscope,

though somewhat improperly: the latter, in frictio, being

an instrument that barely shews an alteration in the weight

of the atmosphere: but it is one thing to know that the

air is heavier at one time than another, and another to

measure how much that difference is: which is the business

of the barometer.

The barometer is founded on the Torricellian experiment,

as it is called from its inventor Torricelli, who, in con-

sequence of the previous suggestion of Galileo, with regard

to the ascent of water in a pump, upon drawing up the

pillow, proceeded, in 1643, to fill with mercury a glass-tube,

hermetically sealed, or closed at one end, the other end

being open and immered in a basin of flagrant mercury.

Judging

that, in the former case, the water was filled in the

pump by the pressure of the air on the water in the vessel,

in which its open end was immered, and that it was the

measure of this pressure, he hence concluded that mercury

would in like manner be supported by it in the tube, and at a

height which was also the measure of the air's pressure, or

about 13 times less than water. His experiment was com-

pletely verified; for he observed that the mercury defended

in the tube, and finally settled at the perpendicular height

of 29 1/2 Roman inches, whether the tube was vertical or

inclined, according to the known laws of hydrostatical

pressure. This famous experiment was repeated and diver-

sified in various forms, with tubes filled with other fluids, such

as water, wine, oil, &c.; and the result being the same, the

weight and pressure of the air were establlished beyond con-

duction or doubt. Those who had any remaining doubts

were completely satisfied by a beautiful experiment exhibited

by M. Azout. He provided a small box or plain

EFGH (Plate IX. Pneumatics, fig. 74) into which he in-

serted two glass tubes, A B, C D, each three feet long,

in such a manner that they were firmly fixed at one

end, and reached nearly to the other end. The tube A B

was open at both ends, and C D was closed at D. This

apparatus being completely filled with mercury, by uncer-

rowing the tube A B, and filling the box and the tube C D,

and then lowering the tube A B and also filling it, was in-

verted, whilst a finger was held on the orifice A, and set up-

right in the manner exhibited in Fig. 75, immering the

orifice A of Fig. 74, or a of Fig. 75, in a small vessel of

quicksilver. Upon this, the mercury ran out at the orifices

A B, till its surface m m within the tube, defended to the

top of the tube b a. The mercury began also to defend in

the tube d e (Fig. 75) corresponding to D C in Fig. 74, and

flowing over into the tube b a, escaped at a, till that in d e

was very nearly on a level with m m. In b a, the mercury

stood at b, 29 1/2 inches above the surface e f of the mercury

in the cistern, as in the Torricellian tube. Indeed, this

whole apparatus may be first considered as a Torricellian

tube of an uncommon form, from which the mercury would

flow out at a. But when any of it escaped, a vacant space

would be left above m m, and the mercury in the tube d e

would also defend, and running over into b a, supply its

waite, till d e became almost empty, and could no longer

supply b a. The inner surface being therefore deprefsed as

much as possible, till it became level with b, no more mer-

cury could enter into b, and yet its column being too heavy

to be supported by the pressure of the air on the mercury in

the cistern e f, it must defend in b a, till it finally settled

at the height e f, equal to that of the mercury in the Torricel-

liian tube. In this state if a small hole g were made in the

upper cover of the box, the external air would rush in by its

weight, and press on the mercury in the box. This pres-

sure would immediately cause the mercury to rife in the tube
to k, 29 1/2 inches above m m. It likewise presses on the

mercury in the box at k in the tube b a, balancing the pressure of the air on

the mercury in the cistern. The mercury in the tube, therefore, must defend to the bottom by its own weight.

By this experiment the doctrine of the gravity and pressure
BAROMETER.

of the air is decisively established. See Air, Weight of, and Experiments with the Air-Pump.

Notwithstanding the satisfactory demonstration of the air's pressure, afforded by the Torricellian experiment, some attempts were made by the advocates of a plenum for evading it, and for explaining the phenomena of this experiment by some other hypothesis. Accordingly Linus contended, that in the upper part of the tube there is a film, or "rope of mercury," whence his hypothesis was called "the funicular hypothesis," which extended through the seeming vacuity; and that, by means of this rope, the rod of the mercury was suspended, and kept from descending into the basin. In proof of this absurd and ridiculous hypothesis he alleged the following experiment. Take, says he, a small tube, about 20 inches long, open at both ends; fill it with mercury, and stop the lower orifice with your thumb. Then clapping the upper end with your finger, immerse the lower end in flagrant mercury; and upon the removal of your thumb, there will be a feizable friction of the finger into the tube; and both the tube and mercury will adhere to it so closely, that they may thus be carried about the room. Hence he infers, that the internal cylinder of mercury in the tube is not suffused by the pressure of the external air; for this, he argues, would not account for the strong friction, and the adhesion of the tube to the finger. If the tube be not quite filled with mercury, but a small interval of air left at the top, after the tube is immersed in flagrant mercury, a considerable friction will be perceived. From these experiments, which actually furnish evidence of the air's pressure, the funicular hypothesis of Linus derived support for some time; but it has been long since exploded. When it was perceived that the mercury on the top of a high mountain suffused, and stood at a lower height than on a plain, and that in the vacuum of an air-pump it descended to the bottom of the tube, this hypothesis could have no advocates. However, an experiment mentioned by Mr. Huygens, in which mercury well purged of its air remained suffused in a tube at the height of 75 inches, fuggled a more considerable difficulty, which has been variously solved. See an account of it, under the article TORRICELLIAN. For an explanation of the phenomenon of a siphon, which discharges water under the exhausted receiver of an air-pump. See SIPHON.

BAROMETER. Common, the Construction of it.—A glass tube (A B. Plav IX. Parumetetic, fig. 75.) open at one end, and hermetically sealed at the other A, having its diameter about one-third or one-fourth of an inch, and its length thirty-three or thirty-four inches, is filled with mercury so finely as not to have any air over it, nor any bubbles adhering to the sides of the tube; which is best done by means of a small paper or glass funnel, with a capillary tube. If a small bubble of air be moved backwards and forwards in the tube, it will help to clear the mercury; which will appear, when pure, like a polished rod of steel. The orifice of the tube, filled after this manner, so as to overflow, is then closely prefled by the finger, so as to exclude any air between it and the mercury, and thus immerged in a vesiil of a convenient diameter, fo however as not to touch the bottom: at the distance of twenty-eight inches from the surface of the mercury are fixed two plates, C E and D F, divided into three inches, called "the scale of variation," and these again subdivided into any number of small parts. Lastly, the tube is inclosed in a wooden frame, to prevent its being broken; the box, though open to the air, secured from dust; and the barometer is complete. As the lowest lation of the mercury in this country is about 28 inches, and the highest about 31 inches above the surface of the mercury in the basin, the former point is the lowest in the scale of variation, and in the common barometers, called "weather-glasses," it is marked formy; and the latter is marked on one side very dry for the summer, and on the other very cold for the winter. To the next half-inch below this highest point are annexed set fair on one side, and set fair on the other. At the height of 30 inches, the word fair is marked on one side, and froid on the other: at 29½ is marked the term changeable both for summer and winter; at 29 are inscribed on the one side rain, and on the other snow; and at 28½ inches are the words much rain on one side, and much snow on the other. Each of these larger divisions is subdivided into ten parts, and by means of a small sliding index adapted to the instrument, the ascent or descent of the mercury may be ascertained for any number of divisions. Each of these tens is again sometimes divided into ten more, or hundredths of an inch, by means of a sliding piece of brass, with a scale called NOVINUS and VERNIER; for the use of which see the terms, and the sequel of this article.

As the common barometer is the best, and most to be depended upon in accurate observations, it may be proper to add some directions for preparing it: they are collected chiefly from the publications of Mutienbrock, Desaguilers, and De Luc on this subject. It appears from many experiments, that the mercury floats higher in tubes of a larger, than in those of a narrower bore; and therefore when observations are made with different barometers, some regard should be paid to the difference of their diameters, and it would be desirable to have them constructed of tubes of the same diameter. The bore of the tube should be large, in order to prevent the effects of the attraction of cohesion; not less than one fourth of an inch; but if they are one-third of an inch diameter, they are better. If a cimeter be used as a resevoir for the flagrant mercury, it should be large in proportion to the diameter of the tube, at least ten times greater; that the addition or subraction of the mercury, contained between the greatest and least altitudes, may not sensibly affect its depth; for the numbers marked on the scale annexed to the tube, shew their distance from a fixed point, and cannot truly indicate the height of the column above the mercury in the cimeter, unless its surface coincide with this point, and be immovable. In order more effectually to preserve the lower surface at the same height from division on the scale affixed to the instrument, the father of the late Mr. George Adams first applied to the barometer a floating gage, by means of which the same sense is rendered the barometer portable, regulates the surface of the mercury in the cimeter, so that it is always at the place from whence the divisions on the scale commence. See Portable Barometer.

The tube should be preferred free from dust till it is used; and for this purpose it may be hermetically sealed at both ends, and one end may be opened with a file, when it is filled. If this precaution has not been observed, the inside should be well cleanly, by washing it with alcohol highly rectified, and rubbing it with a little pith of flanne-ny leather fanned to a wire. The mercury should be pure; and may be purged of its air, by previously boiling it in a glazed earthen pipkin covered close, and when the tube has been uniformly heated and rendered electrical by rubbing it, the hot mercury should be poured into it in a regular current, through a glass funnel with a long capillary tube, so that the air may not have room to pafs between the parts of the quicksilver. M. De Luc directs, as Mr. Orme had practised many years ago in the construction of his improved diag-onal barometers, that the mercury should be boiled in the tube,
tube, as the most effectual method of purging it of its air and moisture. The process is briefly this: he chooses a tube of 21 lines or 3 lines bore, and not exceeding half a line in thickness; he fills it with the sealed end lowest in an inclined position over a charge of a sift of burning charcoal, preceding first the sealed end to the fire, and moving it obliquely over the chafing-dish. As the mercury is heated, the air bubbles appear like so many fluids on the inner surface of the tube, and gradually running into one another, ascend towards the higher parts of the tube, which are not heated; here they are condensed and almost disappear; and after successive emigrations, they acquire a bulk by their union, which enables them at length to escape. When the mercury boils, its parts strike against each other, and against the sides of the tube, with such violence, that a person accustomed to this operation is ready to apprehend their force to be sufficient to break the tube. The mercury is thus freed from all the heterogeneous particles contained in it, together with their surrounding atmospheres, and the air which lines the inside of the tube, which cannot be easily expelled in any other way, is discharged; when this last-mentioned fluid of air is thus expelled, the tube may be afterwards emptied, and filled even with cold mercury, and will be found nearly as free as air as before. The mercury in the tube thus prepared by a determinate quantity of heat, will rise higher than in those of the common form, and the barometers will more nearly correspond with each other; whereas there will be a difference of six or eight lines in the ascent of the mercury in common barometers. When this operation is completed, the mercury generally remains suspended at the top, and will not descend to its proper level without shaking the tube to bring it down. The tubes, which should be chosen not less than three feet long, may now be filled to their proper length.

Barometers of this kind rise uniformly in a heated room; whilst the mercury in those that had been prepared in the common way descended, and in different proportions. When the room cooled, the former descended uniformly, and corresponded with each other; the latter rose with the same irregularity with which they had before descended, nor were they found, at the close of the experiment, to stand at the same relative heights as they did at the beginning of it. The reason of which is obvious, from the effects of heat on the air remaining in unequal quantities; the tubes in the one case, and on the purer mercury in the other.

Another circumstance that requires attention in the construction and use of barometers is the temperature of the air; for unless this remains the same, the dimensions of a given quantity of mercury will be variable; and the altitude of the mercury will be an uncertain measure of the weight of the atmosphere, because it is diluted by heat, and contracted by cold, when probably its weight and precise measure. M. De Luc attended particularly to this circumstance, and contrived to eliminate the effects of heat on the quicksilver in the barometer, when it is used for accurate observations, by means of a thermometer; the scale of which is divided in such a manner as to indicate, with little labour of calculation, the correction to be made on account of heat. As an increase of heat that is sufficient to raise the mercury in the thermometer from the point of melting ice to that of boiling water, will lengthen the column of mercury in the barometer six lines, he divides each line in the scale of the barometer into four parts, each of which may be safely subdivided into four lesser parts, or sixteenths of a line. The scale of the thermometer marking the interval between the freezing and boiling points, and answering to the six lines of the barometer, is divided into nine-six equal parts; each of which will correspond to the sixtieth of a line in the motion of the mercury in the barometer diluted by heat which must be added to or subtracted from the height of the mercury in the barometer, for every degree of the variation of the thermometer so graduated. A scale of this kind, continued above boiling or below freezing water, is annexed to his Portable Barometer and Thermometer. M. de Luc prepared two barometers with their respective thermometers graduated in the manner above explained; he placed one pair in the cellar of one house, and the other pair in the upper room of another house in a lower situation, to as to be exactly on a level with the cellar; he found that the thermometer in the room rose nine degrees, and the barometer 0° of a line higher than those in the cellar; whereas he found, that without allowing for the effect of heat, the difference in the heights of these two barometers would have indicated a difference of about forty-five feet in the heights of these two places, though they were exactly on the same level. M. De Luc's Recherches, &c. vol. i. p. 193—199. See Atmosphere, and the sequel of this article.

The common barometer is a kind of chamber barometer, and serves for observing in a fixed place the changes of the atmosphere; but is not adapted for removal from one place to another, and in this respect differs from the portable barometer. It is sometimes combined with a thermometer, and is sometimes also with a hygrometer, and in this form prepared by the mathematical instrument makers. An instrument of this kind constructed by Meisser, optician in London, is exhibited in fig. 8., and consists of a barometer d., thermometer e., and hygrometer r., all in one metal frame. The thermometers or hygrometers of this apparatus may be conveniently separated from the frame, and occasionally used apart, if it be necessary. The thermometer is separated by means of two levers a. and the hygrometer, by unscrewing a brass pin at the back of the frame. The index of the hygrometer is set at any time, merely by moving with the finger the brass wheel seen at e.; and the two sliding index marks of the barometer and thermometer are moved by rack-and-wheel, set in action by the key j. placed in the holes f. and r. The divisions of the barometer plate are in tenths of an inch from 28 to 31 inches; and the are subdivided into hundredths, by the Nautilus or Vernier scale, placed on a sliding slip of brass, similar to that of the common barometers. This Vernier (fig. 8.2) is divided into ten equal parts, all of which are equal to eleven of those on the scale of inches or to eleven tenths. By this artifice, the height of the mercury at E is evident merely by inspection to the one hundredth part of an inch. For understanding this, it should be considered that the part of 0°th of an inch is the 0°th part of an inch. But every tenth of an inch in the scale B is divided into ten equal parts by the or Vernier A; for since ten divisions on that exceed ten on the scale by one division, than is, by one tenth of an inch, one division on the Vernier will exceed one division on the scale by one tenth part, and two divisions on the Vernier will exceed two divisions on the scale by two tenths, and so on; therefore every division on the Vernier will exceed the same number of divisions on the scale by so many tenths of a tenth, or by so many hundredths parts of an inch. Consequently the ten equal divisions of an inch on the scale B must be considered as to
many ten hundredth parts of an inch, and numbered accordingly, 1, 2, 3, 4, 5, 6, 7, 8, &c. parts of an inch: then the
Vernier gives the unit to each tenth; thus: let the index very
accurately to the top of the surface of the mercury E, and
if at the same time, the beginning of the divison C
coincide with a line of division in the scale B, then it shews
the altitude of the mercury in inches and tenths of an inch
exactly. But if the index line C of the Vernier fall between
two divisons or tenths on the scale B, then there will be a
coincidence of lines in both at that number of the Vernier,
which shews how many tenth parts of that tenth the index
of the Vernier has passed the last decimal division of the
scale. E. G. Suppose the index of the Vernier were to
point somewhere between the six and seventeeth tenth above
30 on the scale; then, if by looking down the Vernier, you
observe the coincidence at number 8, this shews that the al-
titude of the mercury is 30 inches, and 68 parts of a hun-
dredth of another inch, or simply thus, 30.68 inches. See
VERNIER.

The barometer belonging to the house of the Royal Soci-
ety is of the cilmber kind; and the Hon. Mr. Cavendish
prefers this form to that of the pyknom kind, because both
the trouble of observing and the error of observation are
less, as in the latter we are liable to an error in observing
both legs. Moreover he remarks, that the quicksilver can
hardly fail of setting more exactly in the former than in the
latter; for the error in the setting of the quicksilver can
proceed only from the adhesion of its edge to the tides of
the tube. In the latter the adhesion may take place in two
legs, but in the former only in one; and besides, as the air
has necessarily access to the lower leg of the tymbarom-
er, the adhesion of the quicksilver to the tube will
most probably be different according to the degree of dry-
eness or cleanliness of the glasses. It is true, as M. De Luc ob-
erves, that the citalk barometer do not give the true
pressure of the atmosphere; the quicksilver in it being a
little depressed on the same principle as in capillary tubes.
But it appears by calculation, that in the barometer of the so-
ciety, the error arising from the alteration of the height
of the quicksilver in the citalk can scarcely ever amount to
so much as \(\frac{1}{8}\) th of an inch. In this barometer, the
height of the quicksilver is estimated by the top of its con-
vex surface, and not by the edge where it touches the
glasses; the index being properly adapted for that purpose;
and this manner of observing is more accurate than the other.
Phil. Trans. vol. lxvi. p. 381.

As soon as it was discovered that the different heights of
the mercury indicated by the barometer were in some degree
connected with the state of the weather, and that it might
be applied to the purpose of a "weather glass," many at-
tempt were made to render the changes in it more fen-
sible, and so to measure the variations of the weight of
the atmosphere more accurately; and these attempts have
given rise to a great number of barometers of different
structures, deviating from the simplicity of the common
barometer, and at the same time less accurate. Hence the
wheel barometer, diagonal barometer, horizontal barometer,
pendant barometer, &c.

Des Cartes suggered the first method of increasing the
apparent fenibility, or enlarging the scale of variation, of
the barometer, though he did not live to execute it. He pro-
posed a tube \(AB\) (Plate IX. Pneumatics, fig. 77.) about twenty-
seven inches long, terminating in a cylindrical vessel \(CD\); one half of which vessel, connected above with a long tube
of a very small bore, sealed at top, and exhausted of its air,
was to be filled with water extending up into the small tube; the other part of the vessel, and the lower part of the tube,
were to be filled with mercury. Whenever the mercury rose
in the cylinder, it would force up a proportional quantity
of water into the narrow tube, where it would have a
considerably larger range than that of the mercury in the
cylinder; neglecting the weight or pressure of the water,
the motion of the water and of the mercury would be in the inverse ratio of the figures of the diameters
of the vessels containing them. But the water presses on
the mercury according to its height; and therefore if the
whole range of the mercury in the cylinder, or in a common
barometer, were supposed to be two inches, the specific gravity
of water to that of mercury as 1 to 14, and the differ-
cence between the diameters of the cylinder and tube a
maximum or infinite, then the entire scale of variation in
this instrument would be twenty-eight inches; or the extent
of this scale would be to that of the common barome-
ter in the inverse ratio of the specific gravity of water to
that of mercury. It is evident that in practice it would be
somewhat less than twenty-eight inches. Huygens con-
structed a barometer of this kind; but here, though the
column suspended was larger, and consequently the variation
greater, yet the air imprisoned in the water getting los-
sey by degrees, filled the void space in the top, and so ruined
the machine.

Huygens then thought of changing the construction of the
barometer, and of placing the mercury at top, and the water
at bottom, in the following manner: \(ADG\) (fig. 78.) is a
bent tube hermetically sealed in \(A\), and open in \(G\); the
cylindrical vessels \(BC\) and \(FE\) are equal, and about twenty-
ine inches apart; the diameter of the tube is about a line,
that of each vessel fifteen lines, and the depth of the ves-
sels is about ten; the tube is filled with mercury (the com-
mon barometer standing about twenty-nine inches) which
will be suspended between the middle of the vessel \(F\), and
that of the vessel \(B\); the remaining space to \(A\) being
void both of mercury and air; lastly, common water, tinged
with a sixth part of \(\text{aquæ regis}\) to prevent its freezing, is
poured into the tube \(EG\) till it riseth a foot above the mer-
cury in \(DF\).

When the mercury rising above the level of that con-
tained in \(FE\), through the tube \(AD\), becomes a balance to
the weight of the atmosphere, as the atmosphere increases,
the column of mercury will increase, consequently the water
will descend; as the atmosphere again grows lighter, the
column of mercury will descend, and the water ascend. This
double barometer, as it was called, which is nearly the same
with that of Dr. Hooke, will therefore discover much minute
alterations in the air than the common one; for, instead of
two inches, the fluid will here vary two feet; and by en-
larging the diameters of the cylinders, that variation may
be still increased; but it has this inconvenience, besides
others, that the water will evaporate, and so render the al-
terations precacious; though the evaporation be in some
measure prevented by a drop of oil of sweet almonds swim-
mimg at top; the column of water will likewise be sensibly
affected by heat and cold.

The double barometer of Dr. Hooke was invented in the
year 1668, and is described in the Phil. Trans. No. 185.
The invention was claimed by Huygens and De la Hire;
but it sufficiently appears, that Hooke was the original in-
ventor. (See De Luc's Recherches, vol. i. p. 18.) This
conflicts of a compound tube \(ABCDEF\) (fig. 79.), of
which the parts \(AB\) and \(DE\) are equally wide, and \(EFG\)
of which the parts \(AB\) and \(EG\) are made as cylindrical as possible.
BAROMETER.

The part HBCDI is filled with mercury, having a vacuum above in AB. IF is filled with a light fluid, and FG with another light fluid, which will not mix with that in IF. The cilind G is of the same diameter with AB. It is plain that in this instrument the range of the separating surface at P must be as much greater than that of the surface I, as the area of I is greater than that of P; and this ratio may be selected at pleasure. This barometer is the bolt of thole with an enlarged scale; it is most delicately moveable, and is the best adapted to a chamber for the purpose of amusement, by observations on the changes of the atmospheric pressure. It rises or falls by the slightest breeze, and is continually in motion. The most accurate method for graduating such a barometer would be to make a mixture of vitriolic acid and water, which should have a of the density of mercury. Then, let a long tube stand vertical in this fluid, and connect its upper end with the open end of the barometer by a pipe with a branch to which the mouth may be applied. By straining through this pipe, the fluid will rise both in the barometer and the other tube; and the rise of ten inches in this tube will correspond to a defect of one inch in the common barometer. Thus every point of the scale may be adjusted in due proportion to the rest. But nothing except actual comparison can determine what particular point of the scale corresponds to some determined inch of the common barometer. When this is done, the whole becomes equally accurate. It is liable, however, to several inconveniences. Although the heights of the contained fluids are always the same in a constant temperature, nevertheless their weight or pressure on the base is not always the same on account of the difference of their specific gravity; and though there be no sensible difference in the action of these fluids against the sides of the tube, yet there is a continual action, and therefore the movements of this barometer cannot be so free as those of the simple barometer. These differently coloured liquors mingle with one another, and form a deposit on the sides of the tube, so that their respective boundaries cannot always be ascertained with precision. The fluid of this barometer is also subject to evaporation; and heat acts upon the fluids which it contains. On account of these and such defects, others have had recourse to an

Horizontal or rectangular barometer ABECD (fig. 80.); the tube whereof is bent into the form of a square BCD: at the top of its perpendicular leg it is joined to a vessel or cilind AB; and its variations accounted on the horizontal leg CD. Now here the interval, or space of variation, may be made of any extent at pleasure, and so the minute effect in the air become sensible. For the diameter of the tube CD being given, it is easy to find the diameter of the vessel AB, so as that the scale of defect in the tube DC shall have any given proportion to the scale of ascent in the vessel AB; the rule being that the diameter of the vessel is to that of the tube in a subduplicate reciprocal ratio of their scales. The diameters then of CD and AB being given, together with the scale of ascent of the mercury in the vessel, the scale of mercury in the tube is found thus: as the square of the diameter of the tube is to the square of the diameter of the vessel, so reciprocally, is the scale of mercury in the vessel, to the scale of mercury in the tube.

Caffini was the first inventor of this kind of barometer, though the same construction had been thought of, and first published by M. J. Bernoulli, in the year 1710.

This and the preceding contrivance of Huygens are founded on a theorem in hydrostatics; viz. that fluids having the same base, gravitate according to their perpendicular altitude, not according to the quantity of their matter: whence the same weight of the atmosphere supports the quicksilver that fills the tube ACD, and the cilind B, as would support the mercury in the tube alone.

This list, however, with its excellencies, has great defects; for, by reason of the attraction between the parts of the glass and of the mercury (which Dr. Jurin has shown to be considerable), with the length of the scale (emphatically the quantity of motion), and the attrition against its sides, especially in sudden rises and Descents, the mercury breaks, some parts of it are left behind, and the equality of its rise and fall ruined. Some therefore prefer the

Inclined barometer, or diagonal, of Sir Samuel Moreland, where the space of variation is considerably larger than in the common one, and yet the rise and fall more regular than in the others. Its foundation is this: that in a Toricellian tube BC (fig. 81.) inclined at any angle to the horizon, the cylinder of mercury equivalent to the weight of the atmosphere, is to a cylinder of mercury equivalent to the same in a vertical tube, as the length of the tube DC to the perpendicular height DC.

Hence, if the height DC be subtriple, subquadriple, &c. of the length of the tube, the changes in the diagonal barometer will be triple or quadriple, &c. of the changes in the common barometer. This barometer of the scale allows its tube to be inclined to the horizon at a few angle than 45°, without undergoing the inconvenience of the horizontal one.

Mr. Orme, in order to obviate some of the objections to which the diagonal construction of the barometer is liable, purified the quicksilver from its dross and earthy particles by distillation; and when the tube was filled with a certain quantity of mercury, discharged the remaining air by an intense heat sufficient to make the mercury boil; and he continued this operation for four hours. In the process, an innumerable quantity of small particles were emitted, and when no more bubbles rose in the tube, the mercury appeared extremely bright, but sunk lower in the tube than when it first put in, by two inches. Phil. Trans. Abr. vol. viii. p. 455.

The wheel barometer was a contrivance of Dr. Hooke, in 1668, to make the alterations in the air more sensible; the foundation of this is the common vertical barometer, with a large ball above, and turned up at the lower end, with the addition of a couple of weights A and B (fig. 82.) hanging on a pulley, the one of them playing at liberty in the air, the other resting on the surface of the mercury in the inverted tube, and rising and falling with it.

Thus is the motion of the mercury communicated, by means of the pulley, to an index which turns round a graduated circle; and thus the three inches of vertical ascent are here improved to five, six, or more, at pleasure.

But the friction of the axis of this index, and more especially when it has contracted some rust, generally renders this sort of barometer useless; and, at best, the graduation of inches on the circle can only be considered as a scale of motions of the mercury in its tube; for the great variation of the height of the surface of the mercury in the tube below will perpetually falsify the inches and tenths upon the plate above. In a just or standard barometer, the inferior surface of the mercury in the cilind or tube below should either be invariable, or reducible by a pressing screw to a fixed or determinate gauge point.

The wheel barometer has lately been obtruded upon the public by the frowning Italian hawkers in our streets; but the imperfect manner in which these barometers are constructed,
fluctuated, as well as their defective principle, renders them mere mechanical pictures, and not scientific instruments, in the proper sense.

An instrument of this kind, with considerable improvements, has been constructed by Mr. Fitzgerald, F. R. S. It is furnished with two pulleys that move on friction-wheels; each of which turns an index on the centre of a graduated circle. The smaller circle is four inches in diameter, and divided into three equal parts, each of which is again subdivided into fifths; and the changes corresponding to the rise or fall of the mercury from 28 to 31 inches, are marked on the margin of it, as they are on the scales of common barometers. The larger circle is divided into 300 equal parts; and being about 30 inches in circumference, the index belonging to it will mark distinctly the 600th part of an inch in the rise or fall of the mercury.

On the centre of this circle two regители are fixed, which are placed along the index when the instrument is adjusted; one of them is carried round with the index, and left behind on its return; so that their distance will determine the limits of the variation from one observation to another. Phil. Trans. vol. ii. 12th. No. 10.

The pendant barometer, invented by M. Amontons, in 1695, is a machine rather pretty and curious than useful (fig. 83.) It consists of a glass tube, placed vertically, its upper and smaller extremities hermetically sealed; it has no bell or cylinder, its closed figure supplying that defect; for when filled, like the reit, there will be as much mercury sustained as is equivalent to the weight of the atmosphere; and as that varies, the same mercury takes up a different part of the tube, and so becomes of a different weight.

Thus, when the weight of the atmosphere is increased, the mercury is driven up into a narrower part of the tube, by which means its column is lengthened, and for the reason just given, its weight increased. Again, the atmosphere decreasing, the mercury sinks into a wider part of the tube; by which means its column is again shortened, and its pressure accordingly weakened. Thus, the same mercury is still a balance to the atmosphere under all its variations. The inconvenience in this barometer is, that to prevent the mercury and air from changing places, the bore of the tube must be very small; which facility of the bore renders the friction so feebler as to impede its playing.

The marine barometer is a contrivance of Dr. Hooke, in 1702, to be used at sea, where the motion of the waves renders the others impracticable; it resembles that of Amontons invented in 1695. This is nothing more than a double thermometer, or a couple of tubes half filled with spirit of wine; the one hermetically sealed at both ends, with a quantity of common air inclosed; the other sealed at one end, and open at the other.

Now the air, we know, is able to act on the spirit of wine, and raise it, two ways; partly by its gravity, as in the Torricellian tube; and partly by its heat, as in the thermometer. If then the two tubes be graduated, so as to agree with each other at the time when the air is inclosed, it will easily follow, that, wherever the two agree afterward, the pressure of the atmosphere is the same as at the time when the air was inclosed. If in the thermometer open to the air the liquor stand higher, confounding at the same time how much the other is risen or fallen from the other space of heat or cold, the air is heavier; on the contrary, when it is lower, compared with the other, the air is lighter than at the time when the instrument was graduated. Here the spaces answering to an inch of mercury will be greater or less, according to the quantity of the air inclosed, and the smallness of the tubes; and they may be increased almost in any proportion. But it must be remembered, that the density and rarity of the air, on which this machine is founded, do not only depend on the weight of the atmosphere, but also on the action of heat and cold. This, therefore, can never be a just barometer; but may properly enough be called a manometer, or instrument to shew the density of the air. See Manometer.

Nevertheless, the instrument is said to be of good use in giving notice of all bad weather at sea, as also of veerable winds, and of the neighbourhood of ice. Phil. Trans. No. 429. p. 153.

Improved marine barometers. In the bed of the sea barometers, Meffrs. W. and S. Jones apply a small ivory floating gage, or index, to an aperture in the citerin of mercury below; the index floats on the mercury; a mark is cut on its stem, and another on the socket in which it moves; these two marks are brought to a coincidence by turning the screw below; and thus the surface of the mercury in the citerin is made to be just to the divisions of the plate above.

Mr. Nairne, an ingenious artist in London, constructed a marine barometer for captain Phipps, in his voyage to the north pole; the upper part of which was a glass tube, about three-tenths of an inch in diameter, and four inches long, to which another glass tube was joined, with a bore about 1/3 of an inch diameter. These two glass tubes formed the tube of this barometer, which was filled with mercury, and inverted into a citerin of the same. The instrument was fixed in gimbals, and kept in a perpendicular position by a weight fastened to the bottom of it, and was not liable to the inconvenience attending the common barometer at sea. Voyage to the North Pole, p. 123.

The marine barometer, as it is commonly constructed, differs from the common one merely in having the bore of the tube small for about two feet in its lower part, but above that height it is enlarged to the common size. Through the small part of the instrument the mercury is prevented from ascending too hastily by the motion of the ship, and the motion of the mercury in the upper wide part is consequently lessened. Much depends upon the proper suspension of this instrument; and Mr. Nairne has found by experiment the point from which it may be suspended so as not to be affected by the motion of the ship.

We shall here subjoin the description of two kinds of marine barometers, which are constructed by Meffrs. W. and S. Jones of London, and which seem to be well adapted to marine purposes. In Plate X. fig. 86. one of these barometers is represented as supported on its stand in the cabin of a ship, ready for observation; a b c are the folding mahogany legs, about three feet each in length; A is a circular brass plate, with two hollow brass tubes fixed perpendicularly upon it; a gimbal brass ring with its axis is made to turn between these tubes; and on two spiral springs placed in the tubes, the axis of the gimbal ring acts. The barometer frame B is attached inwards to this ring by an axis and two screws, in a position at right angles to the axis in the uprights, yet left free to move; the three legs are screwed down to the floor of the cabin. Whatever heave or motion the ship may receive, the barometer, by its action on the gimbal, on the springs in the tubes, and on its axis, will always tend to keep its vertical position, and as speedily as possible attain to a state of equilibrium; d is a screw that serves to move the slidingNomeo scale upon the plate above; e is a small mahogany door that is fastened on the tube and plate, to prevent them when this instrument is not in use. On the top of the frame there is a pendent brass ring, by which the barometer,
Rom, without the fluid, may be hung on a neck against the wall of a room or side of a cabin: the screw at the bottom of the frame serves to compress the mercury in the cylinder, in order to force it up to the top of the tube, as in the common barometers. By the barometer's being moveable from its stand, and the fluid folding up into a small extent, the whole apparatus may be packed up in a convenient form for carriage.

The principal inconvenience that has been found to attend this barometer has been the ground occupied by the foot in the cabin when the instrument is in use; this being sometimes more than a mariner can spare; and besides, it is liable to be flung against by a headlong by-stander. To obviate this inconvenience, another principle of mounting has been adopted (see fig. 87. The barometer in this figure is in every respect the same as the preceding, but its mode of filling is as follows: on the sides of the frame, at its centre of gravity, are fixed two iron centres: as an axis to these there is fixed a brass frame a, and brass pillar; one end of this pillar is framed on a vertical joint, having only one motion upwards, and checked by a brass socket shoulder below, to keep the pillar and arm in a horizontal position; thus causing the barometer to be suspended in a vertical direction. The length of the pillar and arm together is about 14 inches; the joint socket at the end of the pillar is attached to a strong round brass plate b, about 3 inches diameter, with four counterbore holes for receiving screws, by which the whole instrument may be fixed securely to the side of a cabin, in any convenient or safe situation. When the instrument is in a state of suspension for observation, it will be about 15 inches from the side of the cabin, and being also free to act on its axis of suspension at a, it is evident that notwithstanding any common motion or roll of the ship, the barometer will tend to keep a vertical position, or to recover it after having been agitated. The only circumstance to be apprehended is the possibility that, by a violent motion, the bottom of the barometer should strike against the side of the cabin, and endanger the glass tube; but this is easily avoided by fixing a temporary leather cushion against that part of the cabin against which alone it could strike. When the instrument is not wanted for any observation, while the ship is in motion, it may be moved upwards upon the joint, and it will close to the side of the cabin or wall, and may be buckled fast by a leather stop and buckle, c, attached for that purpose (see fig. 86.), and thus be out of any danger from any person suddenly or unguardedly coming to it; and it will answer the purpose of the common chamber barometer.

M. Pallentin, an ingenious artificer at Paris, accommodates the barometer to nautical uses, by twisting the middle part of the common barometer into a spiral, confining two revolutions: by this contrivance, the impulsion which the mercury receives from the motions of the ship, are destroyed by being transmuted in contrary directions. De Luc's Recherches, &c. vol. i. p. 34.

The flasht barometer, or baroscoop, used by Mr. Boyle, Otto de Gouvric, &c. confined of a large glass bubble, about the size of a large orange, and blown thin as to weigh only 70 grains. This being balanced by a brass weight, in a nice pair of scales, that would turn with the 30th part of a grain, was found to act as a barometer; for this obvious reason, that the surface of the bubble was opposed to a much larger portion of air than that of the brass weight, and consequently was liable to be affected by the varying specific gravity of the atmosphere; so that when the air became specifically light, the bubble descended, and vice versa. Thus (says Mr. Boyle) he could perceive variations of the atmosphere no greater than such as would have been sufficient to raise or depress the mercury in the common barometer an 8th part of an inch. Nevertheless, the two bodies being of equal gravity, but unequal bulk, if the medium in which they equiponderate be changed, there will follow a change of their weight; so that if the air grows heavier, the greater body, being lighter in specific weight, will rise to its original height than the lesser body in the same medium: but if the medium grow lighter, then the bigger body will outweigh the less.

The barometer of Mr. Cuswell, described in the Philosophical Transactions, has been much commended for its accuracy; the structure of it is as follows: suppose ABCD (fig. 88.) a bucket of water, wherein is the barometer spheriform, consisting of a body strm, and a tube eyq. The body and tube are both concave cylinders, communicating with each other, and made of tin, or rather glass. The bottom of the tube eyq has a lead head to sink it, so that the top of the body may just swim even with the surface of the water, by the addition of some grains weights on the top. The water, when the instrument is forced with its mouth downwards, gets up into the tube to the height yq. There is added on the top a small concave cylinder, which we call the pipe, to distinguish it from the other at bottom which we call the tube; this pipe is to sustain the instrument from sinking to the bottom; m is a wire, m s and d e two threads oblique to the surface of the water, performing the office of diagonals. Now, while the instrument sinks more or less by the alteration of the gravity of the air, there where the surface of the water cuts the thread is formed a small bubble, which ascends up the thread as the mercury of the common barometer ascends, and vice versa.

This instrument, as appears from calculation which the author gives, shews the alterations in the air more accurately than the common barometer, by no less than 1200 times. He observes, that the bubble is seldom known to float till a minute; that a small blast of wind that cannot be heard in a chamber will make it float sensibly, and that a cloud always makes it descend, &c.

Mr. Rowning, (Phil. Trans. No. 427, and Syllen of Philosophy, part ii. diff. 4.) has described a barometer, in which the scale of variation may be infinitely extended. ABCD (fig. 89.) is a cylindrical vessel, filled with a fluid to the height W, in which is immersed the barometer SP, consisting of the following parts: the principal one is the glass tube TP (represented separately at tp), whose upper end T is hermetically sealed; this end does not appear to the eye, being received into the lower end of a tin pipe GH, which in its other end G receives a cylindrical rod or tube ST, and thus fits the tube TP. This rod ST may be taken off, in order to put in its stead a larger or a lesser as occasion requires. S is a flat on the top of the rod ST, and serves as an index by pointing to the graduated scale IA, which is fixed to the cover of the vessel ABCD. MN is a large cylindrical tube made of tin (represented separately at me), which receives in its cavity the smaller part of the tube TP, and is well cemented to it at both ends, that none of the fluid may get in. The tube TP, with this apparatus, being filled with mercury, and plunged into the bason MP, which hangs by two or more wires upon the lower end of the tube MN, must be so poised as to rest in the liquid contained in the vessel ABCD; and then the whole machine rises when the atmosphere becomes lighter, and vice versa. Let it now be supposed that the fluid made use of is water; that the given variation in the weight of the atmosphere is such, that by pressing upon the surface of the water at W, the
the surface of the mercury at \( X \) may be raised an inch higher (measuring from its surface at \( P \)) than before; and that the breadth of the cavity of the tube at \( X \), and of the bafon at \( P \), are such, that by this ascent of the mercury there may be a cubic inch of it in the cavity \( X \) more than before, and consequently in the bafon a cubic inch less. 

Now, upon this supposition, there will be a cubic inch of water in the bafon more than there was before, because the water will succeed the mercury to fill up its place. Upon this account the whole machine will be rendered heavier than before by the weight of a cubic inch of water; and therefore will sink, according to the laws of hydrostatics, till a cubic inch of that part of the rod \( W'S \), which was above the surface of the water at \( H' \), comes under it. Then if we suppose this rod to sink that a cubic inch of it shall be 14 inches in length, the whole machine will sink 14 inches lower into the fluid than before; and, consequently, the surface of the mercury in the bafon will be raised more than it was before, by a column of water 14 inches high.

But the preface of 14 inches of water is equivalent to one of mercury; this additional preface will make the mercury ascend at \( X \) as much as the supposèd variation in the weight of the air did at \( P \). This will give room for a second cubic inch of water to enter the bafon; the machine will therefore be again rendered so much heavier, and will subside 14 inches farther, and so on in infinitum. If the rod was so formed that more than 14 inches of it were required to make a cubic inch, the variation of this machine would be negative with respect to the common barometer, and instead of coming nearer to an equilibrium with the air by its ascent or descent, it would continually recede farther from it; but if less than 14 inches of rod were required to make a cubic inch, the scale of variation would be finite, and might be made in any proportion to the common one.

The same author has also contrived a compound barometer, in which the scale of variation shall bear any proportion to that of the common one. \( ABC \) (fig. 93.) is a compound tube hermetically sealed at \( A \), and open at \( C \); empty from \( A \) to \( D \), filled with mercury from thence to \( B \), and from thence to \( E \) with water. It appears from the nature of a fihon, that if \( HH', BB', GG' \) be in the same horizontal line, the column of mercury \( DH \) will be in equilibrio with the column of water \( GE \), and a column of air of the same bafe, and will therefore vary with the sum of the variations of these. He has subjoined a calculation, whence it appears, that if the tubes \( AP \) and \( FC \) are of an equal borse, the variation in this is less than that of the common barometer, in the proportion of 7 to 13; but if the diameter of \( AF \) be to that of \( FC \) as 5 to 1, the variations will be to those of the common barometer, as 175 to 1; but if the proportion of the diameters be greater, the variations will be infinite in respect to those of the common barometer. Of the practical utility of this construction the author had no experience. Rowlins's Nat. Phil. part. ii. diff. 4.

Another contrivance for enlarging the scale of the barometer is exhibited in fig. 91. \( A'B \) is the tube of a common barometer, open at \( B \), and sealed at \( A \); the end of a lever which moves on the fulcrum \( E \). \( D \) is a glass tube fixed, and serving for a ciferon, which is wide enough to admit the free motion of the barometrical tube \( A'B \). When filled with mercury, is nearly counterbalanced by the long end of the lever. When the atmosphere becomes lighter, the mercury descends in the long tube, and the surface of the mercury rising in the ciferon, pushes up the tube \( A'B \), which causes the lever to preponderate, and to point out by its index moving along a circular arc, the most minute variations. This apparatus, however, is subject to the inconvenience of the friction as well as weight of the lever, when put in motion by the rise or fall of the tube \( A'B \). 

Whilst some have endeavoured to enlarge the variations of the barometer, others have endeavoured to make it more certain by reducing the length of the tube. M. Aumonts, in 1688, first proposed this alteration in the construction of barometers, by joining several tubes to one another, alternately filled with mercury and with air, or some other fluid; and the number of these tubes may be increased at pleasure; but the contrivance is more ingenious than useful.

M. Mairan's reduced barometer, which is only three inches long, serves the purpose of a nanometer in discovering the dilatations of the air in the receiver of an air-pump; and instruments of this kind are now generally applied to this use. See Air-Pump, and Gage.

The barometer lately invented by Alexander Keith, Esq. F. R. S. and F. A. S. Edinb., marks the rise and fall of the mercury from two different times of observation. This instrument consists of a glass tube \( A'B\) (fig. 92.) bent in the manner represented in the figure, open at \( D \), and hermetically sealed at \( A \). The length from \( A \) to \( B \) is 8 inches, and its calibre about \( \frac{1}{4} \) of an inch; from \( B \) to \( C \) is \( 3\frac{1}{2} \) inches long, and about \( \frac{1}{4} \) inch calibre; and from \( C \) to \( D \) 4\frac{1}{2} \) inches long, and \( \frac{1}{2} \) inch calibre. The tube is filled with mercury, the length from \( A \) to \( E \) being 29\frac{1}{2} \) inches. When the tube is hung perpendicularly, the mercury will fall from \( A \) towards \( E \), leaving a vacuum from \( A \) to \( B \). When the atmosphere becomes heavier, the mercury falls in the tube \( DC \); and when lighter, it rises. The range of the scale is about 3 inches, being equal to that of a common barometer of the clock construction, which has a bafon with a very broad surface. This instrument moves in a direction contrary to that of the common barometer, the one rising while the other falls. The tube \( DC \) is represented on a larger scale in fig. 93; \( F \) is the float, having the float-wire fixed to it, terminating in a knee at a right angle between the indexes \( L L' \), where it embraces a very small wire stretched along the scale, and thereby raises or lowers them as the mercury rises or falls in the tube \( DC \). The barometer is prepared for observation, by bringing down the one and raising the other index, till both touch the knee of the float-wire. When next observed, the upper index will point out the greatest depression of the mercury, or lightness of the atmosphere; and the lower the greatest rise of the mercury, or weight of the atmosphere since the scale was prepared. By these means, the variations of the atmosphere are more truly pointed out than by the common barometer; for it often happens that during tempestuous weather, or before it, the mercury both rises and falls within a few hours, or during the night time; which variations cannot be noticed by any of the barometers now in use. The sudden fall and rise, or even the rise and fall of the mercury, always denote an extraordinary agitation in the atmosphere. In a common barometer the mercury may be at the same height in the morning that it was the night before; which leads to a conclusion that as there has been no agitation of the mercury, there will be calm or settled weather; but this new barometer will often flow in such cases, that the one float has been raised \( \frac{1}{2} \), and the other depressed so much; which instead of indicating calm weather denotes that tempestuous weather may be expected.

The weight of the atmosphere at great heights might be discovered by suspending this instrument to an air balloon. Edinb. Trans, vol. iv, 1798.
The portable barometer is so contrived, that it may be carried from one place to another without being disfigured; and since it has been applied to the measurement of altitudes, it has undergone many improvements in its construction and appendages. The most common instrument of this kind consists of a tube composed of two pieces, or of two tubes (see fig. 94.): one of these tubes is thirty-four French inches in length, and straight from the top but bent at the bottom in form of a phiphon; the other tube is eight inches long, open at both ends, of the same diameter with the former, and communicating with its open end by means of a cock. When this barometer is carried from one place to another, it is inverted very slowly to prevent the intrusion of any air; the quicksilver rises into the long tube on which the key of the cock is turned; and to preserve the cock from being too much pressed by the mercury, the barometer is conveyed in this inverted posture. When an observation is to be made, the cock is first open; the tube is then turned upright very slowly, to prevent, as much as possible, such vibration of the mercury as would disturb the observation; and according to the weight of the atmosphere, the mercury will fall in the longer branch, and rise up through the open cock into the shorter. The cock is wholly made of ivory, except the key; and is composed of two small ivory cylinders a and b, open through their whole length, and admitting the free passage of the tube, and of a square piece of ivory, thirteen lines long, as many broad, and nine lines thick, having two holes, one for receiving the key d e, and the other in a vertical direction with two short tubes, h, i, at its extremity, adapted to the holes in the small ivory cylinders above mentioned. The most essential part of the cock is the key, which serves to open and close the communication between the two glass tubes. The part of the key that turns within the cock and passes through the opening in c to f, is formed of cork, and the outward part or handle d e, is made of ivory. The cork is firmly fastened to the ivory by means of a broad thin plate of steel, which cuts both the ivory and cork, lengthwise, through the centre, and reaches within to the hole of the key. This plate serves to counteract the flexibility of the cork, and to make it yield to the motion of the handle, although it is compressed in a very considerable degree by the ivory, in order to preserve it tight. But that this compression may not contract the diameter of the hole of the key, it is lined with a thin hollow ivory cylinder of the same diameter with the tubes. The extremities of the tubes are wrapped round with the membrane employed by the gold-beaters covered with fish-glue in order to fix them tight, the one in the lower, and the other in the upper end of the vertical canal of the cock. On the upper end of the shorter tube is fixed, during the intervals of observation, a kind of funnel, with a small hole in it which is shut with an ivory stopple. This is intended for keeping the tube clean, for replacing the mercury that may have escaped through the cock in consequence of any dilatation; and also for replacing the mercury taken out of the shorter tube, after flushing the cock; when any observation is completed; because when the mercury is left exposed to the air, it contracts on its surface a dark pellicle that settles both itself and the tube. The shorter tube should be cleaned occasionally, by a little brush of sponge fixed to the end of a wire adapted to the purpose.

The barometer thus constructed, and described more in detail by the author (Recherches, vol. ii. p. 6, &c) is placed in a long box of sif, the two ends of which are lined within with cushions of cotton covered with leather. This box may be carried on a man's back like a quiver in its natural position, though the inverted position is to be preferred, either walking or riding; and,
should be defended from the rain by a cover of wax-cloth. In order to prevent its being unduly affected by heat, it should be kept at a distance from the body of the man who carries it, and be protected from the sun by an umbrella, when it is near the place of observation. To the apparatus a phialmet should be annexed, in order to ascertain its vertical position, and a three-legged frame or tripod will serve to keep it firm in that position at the time of observation. The scale of this barometer is annexed to the long tube; it commences at a point on a level with the upper end of the short one, and rises in the natural order of the numbers to 21 inches. Below the above point, the scale is transferred to the short tube; and depends upon it in the natural progression of the numbers to 7. The interval of 27 inches, comprehended between the point marked 20 in the upper tube, and that which corresponds to 7 in the lower, is divided into 27 parts, which are inches. These inches are again divided into lines, fourths, sixteenths, and even thirty-sixth parts of lines. The adhesion and friction of the mercury in the tubes will not allow of a more minute subdivision. As the mercury falls in the one tube, it will rise in the other; and therefore the total altitude will be found by adding that part of the scale which the mercury occupies in the long tube, to that part of which the mercury does not occupy in the short one. In estimating, however, the total fall or rise in the long tube, every space must be reckoned twice; because in barometers of this kind, half the real variation only appears in one of the branches.

One of the thermometers, exhibited in fig. 05, is designed for ascertaining the corrections that are to be made in the height of the thermometer on account of any variation in the temperature of the air by heat and cold. For this purpose it is placed near the middle of the longer tube, that it may partake as much as possible of its mean heat. The ball is nearly of the same diameter with that of the tube of the barometer, that the dilatations or condensations of the fluids contained in them may more exactly correspond; and this ball should also be enclosed in wood that it may participate, as well as the barometer, of the heat of the bottom of the box. The scale of the thermometer is divided into 96 parts, between the points of boiling water and melting ice. M. de Luc, having found that an increase of heat, sufficient to raise the thermometer through this interval, augmented the height of the mercury in the barometer, when it was at 27 French inches, precisely fix lines, was led to divide it into 96 equal parts; so that one of these parts corresponded to \( \frac{1}{48} \) of a line in the height of the barometer: and this quantity therefore must be added to or subtracted from the fixed height, for every degree of variation of the thermometer thus graduated. He placed the term \( \sigma \), one eighth part of the above interval above the lower point: so that there are 12 degrees below, and 84 above it; because as 27 French inches express the mean height of the barometer, so the 12th degree above freezing is nearly the mean altitude of the thermometer. Hence by taking these two points, the one for the mean altitude and the other for the mean heat, there will be few corrections necessary for reducing all observations to the same scale, than if any higher or lower points had been taken. The divisions above \( \sigma \) or zero, are considered as positive and denoted by +, and those below as negative and expressed by —.

If the barometer remains at 27 French inches, and the thermometer at 0, according to the above explained graduation, no corrections are necessary. But if, while the barometer continues at 27 inches, the thermometer should rise any number of degrees above 0, so many sixteenths of a line must be subtracted from the 27 inches, in order to obtain the true height of the barometer produced by the weight of the atmosphere, and to reduce this observation to the flat of the common temperature. On the other hand, if the thermometer should fall any number of degrees below 0, while the barometer remains at 27 inches, so many sixteenths must be added to that height in order to obtain the true altitude. These corrections are very simple and easy when the height of the barometer is at or near 27 inches. But if it falls several inches below this point, as the portable barometer frequently must, according to the directions in which it is placed for the purpose of measuring altitudes, the dilatations will no longer correspond with the degrees of heat, after the rate of \( \frac{1}{48} \)th of a line for every degree of the thermometer; because the columns of mercury being shortened, the quantity of fluid to be diluted must be diminished; and, according to a general statement, the quantity of dilatation for the same degree of heat will be as much diminished as the column is shortened. If, then, it should be found convenient to reckon the dilatations by sixteenths of a line, these sixteenths must be counted on a scale, of which the degrees should be as much longer than the degrees of the first scale, as the shortened column of mercury is less than 27 inches, the height to which the length of the degrees of the first scale was adapted. E. C. Let the mercury descend, in consequence of the elevation of the first point, to \( \frac{1}{2} \) inch; and let the thermometer ascend ten degrees above the mean heat; then according to the rule \( \frac{3}{4} \)ths should be deducted from the mean column for this temperature; but ten half-sixteenths only or \( \frac{1}{4} \)ths must be subtracted from the column of 13\( \frac{1}{2} \) inches, because the sum of dilatations will be half that of the former; the quantities of fluid being to one another in that proportion. As it would occasion considerable embarrassment to subdivide the sixteenths of correction into smaller fractions proportional to every half inch of descent in the barometer, the same end may be obtained in a much more easy manner by reckoning the corrections on different scales of the same length, with the degrees longer as the columns of the barometer are shorter. E. G. The degree of correction on a scale applicable to the column of 13\( \frac{1}{2} \) inches will be double in length to those of the same degrees adapted to the column of 27 inches, and consequently the number of corrections will be reduced to likewise one half.

M. de Luc continued, in the manner which he has minutely described (Recherches, vol. ii. p. 26, &c.), on a piece of vellum, scales with these properties for no less than 23 columns of mercury, being all those between 28 inches and 29 inclusive, reckoning from half inch to half inch, within which extremes every practical case will be comprehended. This vellum he wrapped on a small hollow cylinder, including a spring, like a spring curtain, and he fixed it on the right side of the thermometer. The vellum was made to pass from right to left, behind the tube of the thermometer, and to move along its surface. The observer, in estimating the necessary corrections, draws out the vellum till the scale corresponding to the observed altitude of the barometer, touches the thermometer, and he counts them on that scale. The vellum is then let go, and it is gently furled up by the screw. M. de Luc, having provided the necessary apparatus for the accurate mensuration of heights, proceeded to establish by experiment the altitudes corresponding to the different degrees of the mercury; and he made choice of Salève, a mountain near Geneva, about 3000 French feet high, for the scene of his operations. The height of this mountain was twice measured by levelling, and the result of the mensuration, at the interval of six months, gave a difference of only 10\( \frac{1}{2} \) inches. On this mountain he selected no less than 15 different stations, rising at the rate of nearly 200 feet one above another; and here he proposed to make such a number of observations as would
would serve either to establish a new rule of proportion between the heights of places and the densities of the mercury, or to justify the preference of some one of those that had been formerly discovered.

Soon after he had commenced his observations, an unexpected phenomenon occurred. Having observed the barometer, at one of the stations (Recherches, vol. ii. p. 49, &c.) twice in one day, he found the mercury higher in the second observation than in the first; and this variation he naturally ascribed to a change in the weight of the atmosphere, which must have affected his other barometer stationed on the plain in the same manner. But he was not a little surprised when, on examining the rate of the latter barometer, he found that it had purged a contrary course, and that it had fallen while the other rose. As this difference could not proceed from any inaccuracy in the observations, it was so considerable as to discourage his progress and to disappoint his hopes of success, unless he should be able to explain its cause, and to make due allowance for its effects. The experiment was carefully repeated at different periods. An observer on the mountain, and another on the plain, took their respective stations at the rising of the sun, and continued to make their respective observations, both of the barometer and thermometer, every quarter of an hour till the sun set. It was found, that the lower barometer gradually descended for the first three quarters of the day; after which it reascended, till in the evening it stood at nearly the same height as in the morning. But the higher barometer ascended for the first three quarters of the day, and then descended, so as to regain likewise about the same latitude of the sun in the morning. The following theory seems to afford a satisfactory solution of this phenomenon. When the sun rises above the horizon of any place, its beams penetrate the whole of the atmosphere of which that horizon is the base; but falling very obliquely on the greater part of it, they communicate little heat, and consequently produce little dilatation of its air. As the sun advances, his rays become more direct, and the heat and rarefaction of the air increase. However, the greatest heat of the day is not felt when the sun is in the meridian and his rays are most direct, but it increases after mid-day while the place receives more heat than it loses, just as the tide attains not its highest altitude till the moon has proceeded a considerable way to the west of the meridian. Besides the heat of the atmosphere is greatest at the surface of the earth, and seems not to ascend to any great distance above it; and therefore the dilatations of the air occasioned by the sun will be found principally, if not solely, near the earth. A motion of the adjacent air, in all directions, must take place in order to allow the heated air to expand itself. The heated columns, extending themselves vertically, will become longer, and also specifically lighter in consequence of the rarefaction of their inferior parts. As the motion of air, till it rises into wind, is not rapid, these lengthened columns will take some time to dilate their summit amongst the adjacent less rarefied columns that are not so high; at least they will not do this as speedily as their length is increased by the rarefaction of their bases.

In order to apply this theory to the solution of the phenomenon above mentioned, it should be considered, that the barometer on the plain begins to fall a little after morning, because the column of air that supports it becomes specifically lighter on account of the rarefaction occasioned by the heat of the sun. It continues to fall during the three first quarters of the day, because the heat and consequent rarefaction are continually increasing. After this period it rises again, because the cold and condensation coming on, the specific gravity is augmented by the rising in of the adjacent air. Thus the equilibrium is destroyed, and the mercury returns to the altitude of the morning. The barometer on the eminence rises after morning, and continues so to do for three fourths of the day, for two reasons. The density of the column of air is greater near the earth, and decreases as the distance from it increases. The higher therefore we ascend in the atmosphere, we find air specifically lighter. But by the rarefaction of the base of the column that supports the mercury of the barometer on the eminence, the denser parts of that column are raised higher than they would naturally be if left to the operation of their own gravity. On this account, the higher barometer is prefixed with a weight nearly as great as it would sustain, if it were brought down in the atmosphere to the natural place of that denser air now raised above it by the prolongation of the base of the column. The other reason is, that as the rarefaction does not take place at any great distance from the earth, little change is produced in the specific gravity of the portion of the column that preserves on the higher barometer, and the summit of that column dilates itself more slowly than it increases. Thus we see how this barometer must ascend during the first three fourths of the day, and pursue a course reverse to that on the plain. The condensations returning after this time, the denser air subdues, the equilibrium takes place, and the mercury descends to its first position.

This phenomenon suggested to M. De Luc (Recherches, vol. ii. p. 54, &c.) the idea of a second pair of thermometers, in order to measure the mean heat of the column of air intercepted between the barometers. These thermometers are extremely delicate and susceptible. Their tubes being the finest capillary, the glass very thin, and the diameters of the balls only three lines; the balls are filled with the kernels of fine brass wire covered with silk; by this contrivance the air has free access to the balls and sides; and if the direct rays of the sun be intercepted at some distance by a scrap of paper or by the leaf of a tree, the thermometers will quickly mark the true temperature of the air. For the nessesity and utility of these appendages to the author's apparatus, see the sequel of this article.

A new kind of portable barometer for measuring heights has been invented by Dr. J. A. Hamilton, and described in the transactions of the Royal Irish Academy (vol. ii. p. 95). Instead of the leather bag which confines the mercury in the common portable barometer, Dr. Hamilton substitutes a cylindrical cylinder of ivory, about two inches long and upward of one inch in diameter, with a serrated bottom and open top, somewhat contracted into a shoulder that receives internally a found, clean and porous cork, about 3 of an inch in length, and one in diameter, through which the glass tube is nicely inserted and pushed down midway. The construction depends upon this principle, that spongy cork affords a ready passage through its pores to the particles of air, but prevents the escape of quicksilver, melts a very powerful pressure be applied. Nevertheless, as it is not through the pores of that substance, but through the minute interfaces between the cork and the inside of the ivory cylinder, that the air infiltrates itself, some caution and experience are requisite to prevent the stopper from being fitted too tight: nor can the observer be always assured, that the confinement of the cork will occasion no inaccuracy in the results; for it will evidently require a considerable time, through the extremely slender communications, to restore the balance between the external and internal air, if ever that balance can rigorously obtain. Dr.
BAROMETER.

Hamilton gives very copious and circumstantial directions, together with an annexed engraving, for the construction, adjustment, and application of this instrument. AB (fig. 96.) represents a section of the barometer longitudinally, when put together and ready for use. F, the ivory cylinder, CD, the scale, with a vernier that slides in to cover the aperture when the instrument is put by. E, the attached thermometer in its case, and GG the brass caps that secure the ends. AB (fig. 97.) represents a section of the ivory cylinder with its cork C, and its tube T; SS is the surface of the mercury; M its mass; EE the shoulders that keep the cork C in its place; and FF is the bottom that forms in right.

Dr. Hamilton remarks, that mercury is best cleaned by shaking it repeatedly in a phial with fresh portions of water; and the remark deserves attention. For correcting the errors of altitude caused by the fluctuation of the surface of the mercury in the basin, he recommends the computation of tables from the proportion which the aperture of the tube bears to that of the cylinder. His paper contains practical precepts for calculating heights from observations of the barometer, in a form adapted to practice; and he proposes to delineate vertical sections of a country, by means of a series of such observations, made during settled weather. In the same volume (p. 117, &c.) we have remarks and hints for the further improvement of barometers, by Dr. H. Hamilton, dean of Armagh, occasioned by the preceding communication. He observes, that the pores of cork may in time become choked with dust or moisture; and he therefore proposes, that instead of cork, the box should have a top of ivory with a hole to drop in a floating gage, which might be occasionally filled with a peg or screw, to render the instrument safely portable; on which, it would be better, to have a cover screwed over the top of the box, and a hole in it corresponding with that in the box. When these two holes are connected, the box is open; and it is shut, when the holes are removed from each other by turning the cover and screwing it tight to the top of the box; and if there be a plate of soft leather between them, it will be sufficient to keep the mercury when the instrument is agitated by carriage. The dean had a barometer made in this form, and found it to answer all the purposes of an open and of a portable one. Instead of making tables for correcting the error occasioned by the variation of the level of the mercury in the basin, he thinks it would be more convenient to contract proportionally the divisions of the scale. This obvious plan is illustrated at length. It is suggested, that the close barometers would serve just as well at sea as on land; and the hint merits attention; as a marine barometer is still an important desideratum.

Various improvements in the construction and use of the portable barometer, with its annexed apparatus, have been suggested by Sir George Sluckburgh and Gen. Roy; and they have been adopted by several instrument-makers in London. An instrument of this kind, possessing all the advantages of those by Mr. Ramden and M. de Luc, and from its principles free from some inconveniences and errors to which theirs is liable, is constructed by Mr. William Jones, an ingenious artist in Holborn. It is represented in (Pl. XII. fig. 100.) as included in its mahogany case by means of three metallic rings, b, b, b. This case is in the form of a hollow cone divided into three arms or legs from a to e, and is so carved in the inside as to contain readily the body of the barometer; and the arms, when separated, form three firm legs or supports for the barometer, when it is used for making observations. (See fig. 101.) The instrument is suspended at the part of the case, by a kind of improved gimbals, and thus, by its own weight, it will be sufficiently ready when exposed to the weather. In that part of the frame where the barometer tube is visible, a, there is a long slit or opening, so that the altitude of the mercury may be seen against the light, and the vernier piece a brought down to coincide with the edge of the mercury to the greatest possible exactness. When the instrument is placed on its support, the vernier is to be let down, so that the mercury may subside to its proper height; and also a peg at p must be fastened, to give admission to the action of the external air upon the mercury contained in the box b. The vernier piece, or head of observing what is called the zero, or external division of the column of mercury, is by means of a small floating ivory index or item that rises up through the brass box from the etern below in a hole made for that purpose. This will rise and shew itself directly under a small plate and screw fixed over as a cover, and is unfixed to move upwards. With one eye even with the upper surface of the box, the hand at the regulating screw at the bottom of the frame must so turn the screw till the top of the index is very exactly even with the surface; thus will the adjustment for reading off he made after the stations. The vernier piece at a that determines the altitude of the column of mercury is to be brought down by the hand to a near contact, and then accurately adjusted by a small adjusting screw attached to the top of this vernier scale. This barometer has usually two different sorts of scales inserted on it: that on the right at a is a scale of French inches from 19 to 31, measured from the surface or zero of the mercury in the box b below divided into twelve parts of lines, and each line subdivided by the vernier into ten parts, so that the height of the column of mercury may be ascertained to the 32nd part of a French inch. The scale which is on the other side, or the left of observation, is of the same length; but divided into English inches, each of which is subdivided into 20ths of an inch, and the vernier subdivides each 20th into 25 parts so that the height of the mercury is thus ascertained to the 500th part of an English inch (viz. 200 x 25 = 5000). But this vernier is figured double for the convenience of calculation: the first 5 divisions are marked 10, the 20 marked 40, and the 25 marked 50; and each exact division is reckoned as the two thousandths of an inch, which amounts to the same; for 21.5 = the same in value as 21.5 x 25 = 500. A thermometer is always attached to the barometer, and indeed it is indispensably necessary: it is fastened to the body at c, counterpoised by the surface of the frame, which makes it least liable to be broken; the degrees of the thermometer are marked on two scales, one on each side; viz. that of Fahrenheit and Reaumur, scales generally known: the freezing point of the former being at 32, and the latter at 0. On the right hand side of these scales there is a third, called a scale of correction: it is placed opposite to that of Fahrenheit, with the words add and subtrah; and it serves as a necessary correction to the observed altitude of the mercury at any given temperature of the air blown through the thermometer. There are several other valuable appendages to this instrument that cannot be distinctly represented in the figure: but its nature and use may be apprehended from the above description.

In complete observations, such as those to which we now refer, the observer should be provided with two barometers, or rather three, for fear of danger, and two or three separate thermometers. See the sequel to this article.

By very small additional contrivances this instrument may be rendered equally useful for making observations at sea, with any marine barometer that has hitherto been invented.

The editor has been furnished with the following description...
BAROMETER.

ition of the cillen, &c. of the portable barometer, according to the construction of Mr. Hales, lately an eminent instrument-maker in London. A section of the cillen is represented in Plate XII., of Pneumatics, fig. 102. A A A A B B is the cillen: the part A A A A, which contains the quicksilver, is made of leather, and covered with a bottom of leather C, glued on the wooden ring D D. and prefled close over the wooden cylinder by means of the screw at E E, which screws on the brass cover or collar FF that covers the cylindrical cillen AA. This cillen has a flap at the top, as seen at C C, to prevent its filpping, while it presses the ring D D against the wooden cylinder AA. When screwed tight, the quicksilver III is prevented from filpping. If part of the tube of the barometer, drawn nearly to a point, and covered with an ivory cap KK for defending it against injury, I L is a screw with a broad circular top Q Q, by means of which the leather C forces up the quicksilver to as to fill the tube, when the instrument is carried from one place to another. In order to prevent the oscillations of the quicksilver from breaking the tube by sudden jerks, a pin a with a head b b, is through the screw LL; this pin has on the under side of the head a spiral spring to counteract the violence of a sudden motion. The two nuts M N, are used to raise or depress the screw LL, and consequently the quicksilver; the proper height of which is indicated by the floating gage gage, the top of which item P corresponds to the top and outside of the cillen. When the barometer is not in use, the gage and aperture are covered by the plate e, which effectually confines the quicksilver, the under side of b being covered with leather. The lower end of the screw LL is flit up as high as a, and carries a crofs pin d passing through the bottom of the pin a b to prevent it from rising too high. Fig. 103. represents a square frame to be screwed on the part B B fig. 102, and connected by wires from the angles to the legs as seen in the perspective view in fig. 101. This is used to prevent the barometer from vibrating.

The nomis is exhibited at large in fig. 104. A is a screw with a milled head tapped into the piece B B, and also let into and moveable in the piece C in the manner represented at D in fig. 105, which is a side view.

B and C in fig. 106, are horizontal sections of B and C, fig. 104. The spring a of the piece B is considerably stronger than that of C; so that it requires much greater force to make it flie up and down, whilst C, which slides very easily, is moved by turning the milled head E; and thus the lower surface of C is made to coincide with the upper surface of the mercury at F; and, besides, both the piece B and the nomis C may be depressed or raised at pleasure as occasion requires, for a due adjustment of the nomis. B b hind the plate a b, in the respective view fig. 101, hangs a pendulum suspended at the point a which serves for setting the instrument vertical; and when it is brought into this position, a mark on the bob coincides with another on the plate, as seen at b. When the instrument is not in efe, a fork connected with the screw e is pushed up, and prevents the pendulum from flaking.

In order to adapt the portable barometer more completely to the purpose of measuring heights, in which use of it peculiar accuracy of observation is neceffary, it should be furnished with two microscopes or magnifying glasses, one of which should be placed at the beginning of the cillen; and either this should be moveable, so that it may always be brought to the surface of the mercury in the cillen; or the cillen should be so contrived that its surface may always be brought to the beginning of the cillen. By this glasses the coincidence may be accurately perceived. The other microscope must be moveable, so as to be let opposite to the surface of the mercury in the tube; and the scale should be furnished with a vernier, which divides an inch into 1000 parts, and constructed of materials, the expansion of which is precisely ascertained. For an account of many ingenious contrivances to mark the barometer accurate, portable, and commodious, the reader may consult Magellan's "Diff. de Diverses Instr. de Phys." Philos. Trans. vol. xii. vol. xiii. "Journ. de Phys. xvi. 352. xviii. 391. xix. 238. xx. 456. xxx. 350. Sulzer, Act. Helvet. iii. 239. De Luz, Recherches, &c. ubi infra. Cardin. de Luynes, Mem. Par. 1745. Van Swinden's Pohtionen Physic. Comm. Acad. Petrop. i. Id. Nov. ii. 209. viii.

Mr. Magellan, in his edition of "Cromedt's Mineralogy," has shewn that great errors may arise in barometrical measurements for want of due attention to the specific gravity of the mercury with which barometers are filled. If two barometers each 30 inches high, and in every other respect similarly circumstanced, be filled with mercury of different specific gravity, that of the one being 13,620, and that of the other 13,450, the error in the result would be no less than 357 feet: because the heights of the mercurial column in each barometer will be in the inverse ratio of their specific gravities; viz. 13,450 13,620 = 12 = 20,720. But the logarithm of 12 is 4.171,21, and that of 20,720 is 4825,73, neglecting the indices, and their difference is 54,52, which shews that there is a difference of 54,52 fathoms or 327 feet in the altitudes of the two places, where the barometers should have been stationed, though in reality they were on the same level. But if the specific gravity of the mercury in the two barometers were according to the different statements of Bergman and Fourcroy, the one 14,110 and the other 13,000, (and this may happen to be the case, as the heaviest is commonly reputed to be the purest mercury,) the error must have amounted to 35576 toises, or 2154.4 feet, because 13,000 : 14,110 :: 30 : 32,561. But the logarithm of 30 is 4.771,21, and that of 32,561 is 5125,97, and the difference, or 35576, shews that the error should amount to so many fathoms, or 2154,5 feet. See the sequel of this article.

BAROMETER. PHENOMENA OF THE. These are the variations of height in its mercurial column, for ascertaining which many contrivances in the structure of the barometer have been proposed; the principal of which have been detailed in the preceding articles; and the subject will be further pursued in the sequel. The uses to which these phenomena have been subervent, are the prediction of the weather from the variable weight of the atmosphere, indicated by the rise and fall of the mercury in the barometer, and the measurement of altitudes, to which they have been lately applied with singular affinity and success.

The phenomena of the barometer, considered as a "weather-glass," have been very differently stated and explained by various writers; and they are so precarious, that it is extremely difficult to form any fixed and general rules concerning them. Although we have reason to believe, that the barometer never fails to indicate a storm, or any very great change of weather, for some hours before it occurs; yet its variations afford no indications or proyes which are absolutely certain, with respect to those lesser considerable changes, to which the weather is subject in our variable climate. With certain restrictions, they afford some ground for probable conjectures; and these restrictions are to be determined merely by the fugacity of long-continued observation and experience.Strictly speaking the height of the mercury in the barometer hath no immediate and necessary connection either with rain or fair weather. That its variable height is the immediate consequence of the variable
variable prehure of the atmosphere, is a fact that admits of no doubt; but the causes of this variable prehure have not yet been fully and satisfactorily ascertained; and how far the rate of the weather, in all its minute and sudden changes, depends upon it, is a question that still remains to be determined. Mr. Pafcal was one of the first persons who particularly observed the variations of the barometer, and referred them to corresponding changes in the weight of the air; but he acknowledges, that it is very difficult to explain both the one and the other, as well as the connection that subsists between them. He observes, in general, that the mercury is commonly highest in winter and lowest in summer; that it is kalt variable at the solstices, and most variable at the equinoxes: and he adds, in direct contradiction to later experience, that the mercury usaally falls in fine weather, and that it rises when the weather becomes cold or the air is loaded with vapours. Mr. Pafcal was followed by Parrier, Bals, Wallis, Garçin, Garden, Litter, Haly, Gerfet, De la Hire, Mariotte, LeCat, Woodward, Leibnitz, De Maizan, Bernouilli, Mofchenbroek, &c.; all of whom have given different solutions of the phenomena of the barometer.

The principal observations, that have been made on the variations of this instrument, are summed up by Mr. Kirwan (Tenth Trans. vol. ii. p. 46, &c.) in the following particulars:

I. The more considerable elevations and depressions of the mercury in the barometer happen at a very short interval of time in places very remote from each other. This correspondence was observed by Mr. Derham in 1699 between the heights of the mercury at Uptonhall in Essex, and Townly in Lancashire; and afterwards by Mr. Marsili between the variations at Paris and Genoa, at the distance of nearly four degrees of latitude, who adds, during these variations different winds prevailed at these places. But Mr. Kirwan observes, that where there is a considerable difference of longitude, the like agreement is not found.

II. The deviations of the mercury from its mean annual altitude are far more frequent and extensive in the neighbourhood of the poles than in that of the equator. At Peterborough, in 1723, the mercury once stood at the tremendous height of 51,59 inches; if we may credit Mr. Congett, and it has been seen to low as 28,14 inches. In the northern parts of France the variations are greater than in the southern; at Naples they scarcely exceed one inch. In Peru, under the equator, and at the level of the sea, they amount on y to two or three tenths of an inch; but in other parts, within a few degrees of the line, on the approach of the rainy season or of hurricanes, the barometer falls an inch or more.

III. The variations without the tropics are greater and more frequent in the winter than in the summer months.

IV. The variations are considerably smaller in very elevated situations than on the level of the sea. Thus M. Bouger observed, that on the coast of Peru the variations extended to 2 of an inch: at Quito, elevated 9,774 feet above the sea, they comprehend only 0,083 of an inch. M. Sauffiette made similar observations in Savoy, as did Mr. Lambert in Switzerland.

V. The mean height of the barometer on the level of the sea in most parts of the globe hitherto examined, is about 29,970 inches. M. Bouger, under the line, observed it at 29,960 inches; but as his barometer was not purged of air by fire, it stood lower than it should have done. Sir George Shuckburgh (Phil. Trans. vol. lviii. p. 586), on a mean of several observations on the coasts of Italy and England, found it at 30,04, when the temperature of the mercury was 55° and that of the air 62°. The mean height of the barometer in London, upon an average of two observations in every day of the year, kept at the house of the Royal Society, for many years past, is 29,88; the mean temperature or height of the thermometer, according to the fame, being 58°. The greatest height observed by Sir G. Shuckburgh, Dec. 26, 1778, in London, was 30,048 inches, the thermometer being at 47°; and reduced to the heat of 50°, it was 30,057: and this, he says (Phil. Trans. vol. ix. p. 370.), is the greatest height, which, as far as he has been able to collect it, has ever been seen to stand at in any country, where observations have been made and recorded, since the first invention of this instrument. In the proximity of the poles, says Mr. Kirwan, the annual mean heights of the barometer differ much more from the above standard than in the more southern parts of our hemisphere.

In eliminating the connexion of the variations of the barometer with the weather, Dr. Halley has proposed the following rules:

I. In calm weather, when the air is inclined to rain, the mercury is commonly low.

II. In severe and settled weather, and also in calm and frosty weather, the mercury is generally high.

III. Upon very high winds though not accompanied with rain, the mercury sinks lowest, regard being had to the point of the compass from which the wind blows.

IV. The greatest heights of the mercury are found upon Easterly and north-easterly winds; other circumstances being alike: to which it may be added, that under a southerly wind it is commonly low. The above four observations made by Dr. Halley in England, seem to be most universal, as they were found by Mr. Melander (Scheved. Abhand. 1773, S. 255) to apply to lat. 30°, and by M. de Luce to lat. 46°.

V. After very great storms of wind, when the mercury has been very low, it generally rises again very fast.

VI. The more northerly places have greater alterations of the barometer than the more southerly.

VII. Within the tropics, and near them, there is little or no variation of the mercury in all wheather. At St. Helena it is little or nothing; at Jamaica 3/6 of an inch; whereas in England it amounts to 2 inches, and at Peterborough to 3.1 inches.

Dr. Beal, who adopted the opinion of M. Pafcal, observes that, e litter paribus, the mercury is higher in cold weather than in warm; and usually in the morning and evening higher than at midday: that, in settled and fair weather, it is higher than either a little before or after or in the rain; and that it generally descends lower after rain than it was before it. And he ascribes these effects to the vapours with which the air is charged in the former cafe, and which are dispersed by the falling rain in the latter. If it chance to rise higher after rain, it is generally followed by a settled ferocity. He adds, that there are frequently great changes in the air, without any settled alteration in the barometer.

An ingenious author observes, in relation to this use of barometers, that, by their means, we may regain the knowledge, which still resides in brutes, and which we have forfeited by not continuing in the open air as they generally do: and by our intemperance corrupting the crafts of our organs of sense.

Mr. Patrick's rules for judging of the weather by the rise and fall of the mercury in the barometer, have been much approved, and are to be accounted for on the same principles with those of Dr. Halley. They are as follow:—1. The rising of the mercury prelages, in general, fair weather; and
BAROMETER.

and its falling, foul weather; as rain, snow, high winds, and storms.

2. In very hot weather, the fall of the mercury indicates thunder.

3. In winter, the rising preeages frost; and in frosty weather, if the mercury falls three or four divisions, there will certainly follow a thaw: but in continued frost, if the mercury rises, it will certainly snow.

4. When foul weather happens soon after the falling of the mercury, expect but little of it: and on the contrary, expect but little fair weather, when it proves fair shortly after the mercury has risen.

5. In foul weather, when the mercury rises much and high, and so continues for two or three days before the foul weather is quite over, then expect a continuance of fair weather to follow.

6. In fair weather, when the mercury falls much and low, and thus continues for two or three days before the rain comes; then expect a great deal of wet, and probably high winds.

7. The unsettled motion of the mercury, denotes uncertain and changeable weather.

8. You are not to strictly to observe the words engraven on the plates (though for the most part it will agree with them), as the mercury's rising and falling; for if it stands at much rain, and then rises up to changeable, it preages fair weather, although not to continue so long as it would have done, if the mercury were higher: and so, on the contrary, if the mercury stood at fair, and falls to changeable, it preages foul weather, though not so much of it, as if it had sunk down lower.

From these observations appears, says Mr. Rowing (Nat. Philos. part ii. diff. 4.), that it is not so much the height of the mercury in the tube that indicates the weather, as the motion of it up and down: wherefore in order to pass a right judgment of what weather is to be expected, we ought to know whether the mercury is exactly rising or falling, to which end the following rules are of use:

1. If the surface of the mercury is convex, standing higher in the middle of the tube than at the sides, it is generally a sign that the mercury is then rising. And,

2. If the surface of the mercury is concave, or hollow in the middle, it is sinking. And,

3. If it is plain or level, or rather if it is a little convex, the mercury is stationary; for mercury being put into a glass tube, especially a small one, will naturally have its surface a little convex; because the particles of mercury attract each other more forcibly than they are attracted by glass. Further,

4. If the glass be small, shake the tube; and if the air be growing heavier, the mercury will rise about half the tenth of an inch higher than it stood before; if it is growing lighter, it will sink so much. This proceeds from the mercury sticking to the sides of the tube, which prevents the free motion of it, until it is disengaged by the shock. Therefore, when an observation is to be made by such a tube, it ought always to be shaken first; for sometimes the mercury will not vary of its own accord, until the weather it ought to have indicated be present.

To the preceding rules we may subjoin the following, deduced from the latter and more accurate observation of the motions of the barometer, and the consequent changes in the air of this country:

1. In winter, spring, and autumn, the sudden falling of the mercury, through a large interval, denotes high winds and storms; but in summer it denotes heavy showers, and often thunder; and it always sinks lowest of all for great winds, though not accompanied with rain; though, however, it falls more for wind and rain together, than for either of them alone. Also, if, after rain, the wind change into any part of the north, with a clear and dry sky, and the mercury rise, it is a certain sign of fair weather.

2. After very great storms of wind, when the mercury has been low, it commonly rises again very fast. In settled fair and dry weather, except the barometer sink much, expect but little rain; for its small sinking then is only for a little wind, or a few drops of rain; and the mercury soon rises again to its former station. In a wet feason, suppose in hay-time and harvest, the smallest sinking of the mercury must be regarded; for when the constitution of the air is much inclined to showers, a little sinking in the barometer then denotes more rain, as it never at this time stands very high. And if, in such a feason, it rises suddenly, very fast, and high, expect not for weather more than a day or two, but rather that the mercury will fall again very soon, and rain immediately follow. The slow gradual rising, and keeping on to do so for two or three days, are most to be depended upon for a week's fair weather; and the unsettled state of the quicksilver always denotes uncertain and changeable weather, especially when the mercury stands any where about the word changeable on the scale.

3. The greatest heights of the mercury, in this country, are found upon easterly and north-easterly winds; and it may often rain or snow, the wind being in these points, and the barometer may sink but little or not at all, or it may even be in a rising state, the effect of those winds counteracting. But the mercury sinks for wind, as well as for rain, in all the other points of the compass; but it rises as the wind shifts about to the north or south, or between those points: but if the barometer sink with the wind in that quarter, expect it soon to change from thence: or else, if the fall of the mercury should be considerable, a heavy rain is likely to ensue, as it sometimes happens.

BAROMETER, Cause of the Phenomena of the. Those which have been enumerated, are the chief phenomena of the barometer; to account for which, the hypotheses that have been framed are almost innumerable. It would far exceed our limits to detail them all; we must content ourselves with briefly reciting some of the principal, and refer the reader who is desirous of further information to De Luc's "Recherches," vol. i. ch. ii.

Some, as Pascal, Beal, Wallis, and Garcin, have accounted for the change in the weight of the air by the augmentation of the atmosphere in consequence of the introduction of vapours, and its diminution by their fall; others, as Pierrier, Garden, Le Cat, and De Mairan, have ascribed it to the variations of heat; and others, as Garden, to the alterations of the specific gravity of the air; and Dr. Hailey refers it to the accumulation or dispersion of the air by contrary winds. Wallis, Halley, and De Mairan have supposed that there is a difference in the vertical pressure of the air, when in motion and at rest. Wallis, and some other philosophers, have conceived that the height of the barometer depends upon the variations that occur in the elasticity of the air, and that it is directly proportional to these variations. Some have also had recourse to the contractions and dilatations of the mercury itself, as Wallis and Lider; others, as Gerlert, suppose vibrations produced in the particles of air by the winds. De la Hire and De Mairan imagine that air is removed from the south to the north, and from the north to the south: Mariotte supposes that the inclination of the winds to the surface of the earth is sometimes greater and sometimes less. Woodward and Hamberger conceive that there is a shock of vapours against the air, when they rise, and that this ceases when they are at rest. Leibnitz sup-
poses that there is a diminution in the weight of the air when rain falls; and De Mairain apprehends, that an agitation of the air is occasioned by vapours; and Bernouilli is of opinion, that an augmentation of the atmosphere is produced by a dilatation and discharge of the air enclosed within the bowels of the earth, and that there is a diminution of it when the contrary happens. To these several causes acting separately or conjointly, and to several circumstances attending their different operation, the vibrations of the barometer have been attributed. But these causes may all be reduced to three general classes: viz., variations of temperature; the velocity and other qualities of different winds; and the agency of vapour.

Dr. Lister accounts for the changes in the barometer from the alterations of heat and cold. This, he says, he has often observed, that in storms, &c. when the mercury is at its lowest, it breaks, and emits small particles, which he calls a kind of fretting; and argues, that in all times of its descent, it is more or less on the fret. In this disorder, he thinks, its parts are contracted, and brought closer together; and for that reason, defend ed: b. sides, in the fretting they let go little particles of air, before inclosed in them, and these riling into the top of the tube, the mercury must fall, both from the column’s being shortened by their escape, and by their lying upon it. Mercury therefore, he adds, rises either in very hot or very cold weather, between the tropics, &c. as being then in its natural state; and again, in the intermediate degrees of heat and cold it falls, as being contracted, and as it were convulsed, and drawn together. Phil. Trans. N° 105. But his account, however ingenious, yet comes far short of accounting for the phenomena; nay, in some respects it contradicts them.

The changes in the weight of the atmosphere, therefore, must be laid down as the cause of those in the barometer; but then, the cause of that cause, or whence those alterations arise in the atmosphere, it will be no easy matter to determine; there being, perhaps, no one principle in nature that will account for such a variety of appearances, and those too so irregular. It is probable the winds, as driven this or that way, have a great share in them; some share too, vapours and exhalations, rising from the earth, may have; some, the changes in the air of the neighbouring regions; and some, the flux and reflux occasioned in the air by the moon; and also some chemical causes operating between the different particles of matter.

Dr. Halley thinks the winds and exhalations sufficient; and, on this ground, gives us a rationale of the barometer. The substantive of what may be laid on that head, is as follows:

1 lye, The cold nitrous particles, and even air itself condensed in the northern parts, and driven elsewhere, must load the atmosphere, and increase its pressure.

2 lye, Heavy dry exhalations from the earth must increase the weight of the atmosphere, and heighten its elastic force, as we find the specific gravity of leaden minerals increased by diffused fogs and metals.

4 lye, The air is rendered heavier from these and the like causes, is thereby the more able to support the vapours; which being likewise intimately mixed with it, and swimming every where equally through it, make the weather serene and fair; and the air being rendered lighter, from the contrary causes, it becomes unable to support the vapours where with it is replete; these, therefore, precipitating, are gathered into clouds, and those in their progress, coalesce into drops of rain.

These things observed, it appears pretty evident, that the same causes which increase the weight of the air, and make it more able to support the mercury in the barometer, do likewise occasion a serene sky, and a dry season; and the same causes which render the air lighter, and less able to support the mercury, do likewise generate clouds and rain. Hence, 1 l. When the air is lighter, and the mercury in the barometer is lower, the clouds are very low, and move swiftly; and when, after rain, the clouds break, and a calm sky again thins forth, being purged of the vapours, it appears exceedingly bright and transparent, and affords an easy prospect of remote objects.

2 lye, When the air is heavier, and the mercury stands high in the tube, the weather is calm, though somewhat less clear, because the vapours are dispersed everywhere equally; if any clouds now appear, they are very high, and move slowly; and when the air is heaviest of all, the earth is frequently found enveloped in pretty thick clouds, which appear to be formed out of the greater exhalations, and the weight of which is too strong for the, though a lighter atmosphere could not.

3 lye, Hence it is, that with us the mercury stands highest in the coldest seasons, and when the wind blows from the north or north-east corner; for in that case, there are two winds blowing towards us at the same time, and from opposite corners; there being a constant west wind found in the Atlantic ocean, at the latitude corresponding to ours. To which we may add, that in a north wind, the cold condensed air of the northern parts is brought hither.

4 lye, Hence in the north-east regions, the variation of the mercury is more sensible than in the southern ones; the winds being found more strong, more frequent, more various, and more opposite to each other in the former, than in the latter.

5 lye, Hence it is, that between the tropics, the variation of the mercury is scarcely sensible; the winds there being extremely gentle, and usually blowing the same way.

6 lye, Hence it is, that in those places where we have the particular causes of the barometer, seems to come short of some of the principal and most obvious ones; and, besides, liable to several objections.

For 1 l., if the wind were the sole agent in effecting these alterations, we should have no alterations without a sensible wind, nor any wind without some alteration of the mercury; both which are contrary to experience.

7 lye, If two winds be supposed blowing from the same place, viz. London, opposite ways, viz. N.E. and S.W., there will be two others, blowing from opposite points, viz. N.W. and S.E. to the same place; which two last will balance the first, and bring as much air towards the point, as the others swept from it. Or thus, in proportion as the air
BAROMETER.

is carried off N.E. and S.W. the adjacent air will crowd in from the other points, and form a couple of new currents in the direction N.W. and S.E. to fill up the vacancy, and restore the equilibrium. This is a necessary consequence from the laws of fluids.

Andly. If the wind were the sole agent, the alterations in the height of the mercury would only be relative, or topical; there would be still the same quantity supported at several places taken collectively: thus, what a tube at London lost, another at Paris, or at Pisa, or at Zurich, &c., would at the same time gain. But we find the very contrary true in fact; for from all the observations hitherto made, the barometers in several parts of the globe rise and fall together; so that it must be some alteration in the absolute weight of the atmosphere that accounts for the rise and fall of the mercury.

Lastly. Setting aside all objections, these popular phenomena, the mercury's fall before, and rise after rain, seem to be inexplicable on the ground of this hypothesis; for suppose two contrary winds sweeping the air from over London, we know that few, if any, of the winds reach above a mile high; all, therefore, they can do, will be to cut off a certain part of the column of air over London: if the consequence of this be the fall of the mercury, yet there is no apparent reason for the rain's following it. The vapours indeed may be let lower, but it will only be till they come into an air of the same specific gravity with themselves; and there they will be elevated as before.

M. Leibnitz, about the year 1710, in a letter written to the abbe Bignon, endeavoured to supply the defects of this hypothesis with a new one of his own. The new principle, upon which Leibnitz's hypothesis is founded, was illustrated by M. Fontenelle in the Histoire of the Royal Academy of Sciences at Paris for the year 1711. He afferts, that a body immersed in a fluid only weighs with that fluid while it is unfattained by \( \pi \), that is when its surface is greater than the weight of the air, by \( \pi \). Thus, when let fall, its weight ceases to make a part of that of the fluid, which by this means becomes lighter. Thus, adds he, the watery vapours, while unfattained in the air, increase its weight; but when let fall, they cease to weigh along with it. Thus the weight of the air is diminished; and thus the mercury falls, and rain ensues.

But M. Leibnitz's principle, notwithstanding the experiment he brings to confirm it, is false, as has been evidently made appear by a counter experiment of Dr. Delfaguier. (See his Course of Exp. Philol. vol. i. p. 282, &c.) For a body, whether specifically equal or lighter or heavier than a fluid, while it is immersed in it, whether it be at rest, or in motion, adds to the fluid a weight equivalent to that of an equal bulk of the fluid; as follows from that law in hydrostatics, that fluids gravitate according to their specific gravity.

However, were M. Leibnitz's principle true, yet it is defective; and that in the same respect with Dr. Halley's; nor would it account for the phenomena more than the other. For, supposing the vapours by being condensed, to be put in a motion downwards, and to ceasing to gravitate with the atmosphere; they will therefore fall, till they reach a part of the atmosphere of the same specific gravity with themselves; and there they will hang as before. If the mercury fall, it will only be during the time of that defect; for these once fixed, the former gravity is retrieved; or, were it not retrieved, yet no rain would succeed the fall of the mercury.

The hypothesis, propounded by Mr. Chambers, is somewhat similar to that of Leibnitz, and liable to the same objection. It is as follows: suppose any number of watery vehicles floating in any part of the atmosphere, over any determinate portion of the globe; if the upper vehicles be condensed by the cold of the superior regions, their specific gravity will be increased, and they will descend; where meeting with other vehicles not yet precipitated, they will coalesce, or run into larger vehicles, by the known laws of attraction. Or, if we rather choose to have the wind set, let it drive either horizontally or obliquely, some vehicles will be driven against others; by which means likewise will the particles coalesce, and form new and larger vehicles as before; so that their number, which before was, suppose a million, will now be reduced, v. g. to a hundred thousand.

But by the same coalition whereby their number is diminished, their specific gravity, if we may so call it, is increased, i.e. they come to have more matter in the same space, or under an equal surface; as may be easily proved from principles of geometry: for in augmenting the mass of any homogeneous body, the increase of surface does not keep pace with that of the solidity; but that of the former is as the square of the diameter, and that of the latter as the cube of the former.

But since the same quantity of matter is now in a less space or under less dimensions, it will lose less of its weight by the resistance of the medium. This is evident; for a body immersed in a fluid loses nothing of its weight but by the friction of its parts against those of the fluid; but the friction is evidently as the surface; therefore, when the surface is increased, the resistance must be too. Consequently, the vehicles, whose gravity before the coalition was equal to the resistance of the medium, now that resistance is diminished, will descend; and that with a velocity in the ratio of the increase of the masses to the increase of the surface.

In their descent, as they arrive at denser parts of the atmosphere, their mass and surface again will be increased by new coalitions; and thus, by constant fresh acreions, more than equal to the constant resistances, they will be enabled to pursue their journey through all the regions of the air, till they reach the earth; their masses exceedingly magnified, and in the form of rain.

Now that the vapours have got down, let us consider how the barometer must have been affected during their passage.

Before any of the vehicles began to subside, either from the action of the cold, or of the wind, they all floated in a certain portion of the atmosphere, and all gravitated towards the centre. Here now, each respectively residing in a part of the medium of the same specific gravity with itself, will lose as much of its weight as is equal to that of a part of the medium of the same bulk with itself, i.e. each will lose all its weight. But then, whatever weight each loses, it communicates to the medium, which now preffes on the surface of the earth with its own weight and that of the vehicles conjunctly. Suppose then this united pressure keeps up the mercury in the barometer at thirty inches: by the coalition of the vehicles from the regions aforesaid, their surfaces, and consequently their resistance, are lessened; therefore, they will communicate less of their weight to the air, i.e. less than the whole; and consequently they will descend with the excess, i.e. with a velocity equal to the remainder, as before observed. Now, as the vehicles can act no otherwise on the surface of the earth but by the mediation of the interjacent air, in proportion as their action on the medium is less, their action on the earth will be less. It is also evident, that the surface of the earth must be now less preffed than before; and that in proportion as the vehicles refuse more of their weight communicated to the medium, to promote their own descent, i.e. in proportion to the velocity of the falling vehicles; which is
BAROMETER.

again in proportion to their bulks. Thus, as the vehicles descend, the bulks continually increasing, the friction, and therefore the pressure on the earth, and lastly the height of the mercury, will continually decrease, during the whole time of the fall.—Hence we infer, both why the vehicles, when once beginning to fall, per perreuse; why the mercury begins to fall at the same time; and why it continues and ceases to fall together with them; which were the great objec

There is one objection that evidently lies against this theory, viz. that the vehicles being put in motion, and striking against the particles of the medium and one another with force, moment, will meet with a considerable resistance from the *air* that remains, by which means their descent will be retarded, and the pressure of the atmosphere retrieved; the impetus of the moving vehicles being supposed to compen- sate for their loss of surface. Thus a heavy body sustained in a fluid by a hair, and moved up and down therein, prefers more on the bottom than when held at rest; which additional pressure will be the greater as the velocity of the falling vehicles is greater; a greater impulse being required to break through the *air* that is continually of the contiguous particles in a less time than in a larger.

But it is alleged, that we have both reason and experiment against this objection; for the velocity of the vehicles, in these circumstances, must necessarily be very small, and their impulse insensible; besides, the *air* that remains in the air must be exceedingly weak, by reason of its extreme fluidity: and it must be a very improper vehicle to convey an impulse to a distance by reason of its elasticity; we also find that a piece of lead, which is a ponderous body, falling with great moment, gravitates considerably less, in its descent through water, which is a gross undiffusible medium, than when sustained at rest therein; in which the several experiments of Reaumur, Ramazzini, and D. Franklin, all agree.

M. de Lus (Recherches, &c. vol i. p 138.) supposes that the changes observed in the weight of the atmosphere are principally produced by the presence or absence of vapours floating in it. Others have attributed the effect to vapours, but have given a different explication of it. It is his opinion, that vapours diminish the specific gravity, and consequently the absolute weight of those columns of the atmosphere into which they are received, which, notwithstanding this admixture, remain of an equal height with the adjoining columns that consist of pure or dry air. He afterwards more largely explains and vindicates this theory, and applies it to the following of the principal phenomena of the barometer, connected with or produced by the varying density and weight of the atmosphere.

Dr. James Hutton, in his "Theory of Rain" (see Rain), printed in the Edinburgh Transactions, vol. i. p. 41, &c. suggests several plausible reasons in favour of his opinion, that the diminution of the weight of the atmosphere by the fall of rain is not the cause of the fall of the barometer; but that the principal, if not the only cause, is to be sought for in the communions of the atmosphere that are chiefly produced by sudden changes of heat and cold in the air. "The barometer," he says (p. 78.), "is an instrument necessarily connected with motions in the atmosphere; but it is not equally affected with every motion in that fluid body. The barometer is chiefly affected by those motions by which there are produced accumulations and abstractions of this fluid, in places or regions of sufficient extent to affect the pressure of the atmosphere upon the surface of the earth. But as every commotion in the atmosphere may, under proper conditions, be a cause for rain, and as the want of commotion in the atmosphere is naturally a cause of fair weather, this instrument may be made of great importance for the purpose of meteorological observations, although not in the certain and more simple manner in which it has been, with the increase of science, so successfully applied to the measuring of heights."

In the "Encyclopædia Britannica," art. Barometer, we have another theory of changes in the barometer, as depending on the heat in the atmosphere, not as producing communions in it, but as altering the specific gravity of the air by the variations of heat and cold. The preliminaries to this hypothesis are: 1st. That vapour is formed by an intimate union between the elements of fire and water, in consequence of which the fire or heat is totally enveloped, and its action is entirely extinguished by the water molecules, that it not only loses its properties of burning and of giving light, but becomes incapable of affecting the most sensible barometer, in which case, it is said by Dr. Black, the author of this theory, to be in a latent state. 2dly. If the atmosphere be affected by any unusual degree of heat, it thence becomes incapable of supporting so long a column of mercury as before, for which reason the barometer falls.

From these primary principles or axioms it is inferred, that as vapour is formed by an union of fire with water, whether by an elective attraction or a solution of the water in the fire, the vapour cannot be condensed till this union, attraction, or solution be at an end. Hence it follows that the commencement of the condenstion of the vapour, or the first signs of approaching rain, must be the separation of the fire which is latent in the vapour. This may at first be flow and partial, or it may be sudden and violent; in the first case the rain will come on slowly, and after a considerable interval; in the other it will come on very quickly and in a great quantity. But Dr. Black has proved, that when fire quits its latent state, however long it may have lain dormant and insensible, it always re-attains its proper qualities, and affects the thermometer as if it had never been absorbed. The consequence of this must be, that in proportion the latent heat is discharged from the vapour, those parts of the atmosphere into which it is discharged, will be sensibly affected by it; and in proportion to the heat communicated to those parts, they will become specifically lighter, and of coarse the mercury will sink. When the separation between the fire and water is gradual and slow, the barometer may indicate rain for a considerable time before it happens; or if the sensible heat should be absorbed by the colder parts of the atmosphere, or by any means be prevented from affecting the specific gravity of the air, the barometer will not be affected; and yet the water, deprived of the heat, that is necessary for sustaining it, must descend in rain; and hence it happens, that the indications of the barometer are not always just. Hence it also appears, that though the specific gravity of the air is diminished, unless this diminution proceeds from a discharge of the latent heat contained in the vapours, no rain will follow; and thus the sinking of the barometer may prognosticate wind as well as rain, or sometimes no change at all. The great descent of the mercury in the barometer between the tropics in the time of hurricanes, noticed by Dr. Halley, is ascribed, as to its probable cause, to a great commotion in the electric fluid, by which the air is internally agitated, and its gravitation in part suspended.

In the fourth volume of the "Memoirs of the Literary Society of Manchcr," we have a curious paper on this subject, viz. "Meteorological Observations made in different parts of the Western Coast of Great Britain," arranged by T. Garnett, M. D. The materials of this paper were furnished by several observers; but those of Mr. Copland,
BAROMETER.

Copland, surgeon at Dumfries, are of peculiar importance. This gentleman is of opinion that the changes of the barometer indicate approaching cold and hot weather, with much greater certainty than dry and wet. "Every remarkable elevation of the barometer, he says, when it is of any duration, is followed by very warm or dry weather, and moderate as to wind, or by all of them; but heat seems to have most influence and connection; and when it is deficient, the continuance of the other two will be longer and more remarkable; therefore the calculation must be in a compound ratio of the excess and deficiency of the heat and of the dryness of the weather in comparison of the medium of the season; and with regard to the want of strong wind, it appears to be intimately connected with the fall, as they show that no precipitation is going on in any of the neighbouring regions." 

In his 14th and 15th remarks, he had said,

14th. That the barometer being lower, and continuing so longer than what can be accounted for by immediate falls, or stormy weather, indicates the approach of very cold weather for the season; and also cold weather, though dry, is always accompanied by a low barometer, till near its termination.

15th. That warm weather is always preceded and mortly accompanied by a high barometer; and the rising of the barometer in the time of broken or cold weather, is a sign of the approach of warmer weather: and also if the wind is in any of the cold points, a sudden rise of the barometer indicates the approach of a bitterer wind, which in winter generally brings rain with it.

In the two following remarks Mr. Copland had explained certain phenomena from a principle similar to that on which Dr. Darwin has so much insisted. (Botanic Garden, I. notes p. 79. &c.)

' That the falling of the barometer may proceed from a decomposition of the atmosphere occurring around or near that part of the globe where we are placed, which will occasion the electricity of the atmosphere to be repelled upwards in fine lambent portions; or driven downwards or upwards in more compacted balls of fire; or lastly, to be carried along with the rain, &c. in an imperceptible manner to the surface of the earth; the precipitation of the watery parts generally very soon takes place, which diminishes the real gravity of the atmosphere, and also by the decomposition of some of the more active parts, the air loses part of that elastic and repulsive power which it formerly possessed, and will therefore resist with less force on the mercury of the barometer than before, by which means a fall ensues.

' That the cause of the currents of air, or winds, may also be this way accounted for: and in very rarefied storms, where great decomposi of the atmosphere take place, this is particularly evident, such as generally occur in one or more of the West India islands at one time, a great loss of real gravity, together with a considerable diminution of thepring of the air immediately ensues; hence a current commences, first in that direction whence the air has most gravity, or is most disposed to undergo such a change; but it being soon relieved of its superior weight or spring on that side, by the decomposition going on as fast as the wind arrives in the island, it immediately veers to another point, which then rotes in mortly with an increase of force; thus it goes on till it has blown more than half round the points of the compass during the continuance of the hurricane.

For in this manner the West India phenomena, as well as the alteration of the wind during heavy rains in this country, can only be properly accounted for.' See remark, No. 4.

Mr. C.'s 4th aphorism is, 'That the heaviest rains, when of long continuance, generally begin with the wind blowing calmer, when it gradually veers round to the south; and that the rain does not then begin to cease till the wind has got to the west, or rather a little to the northward of it, when, it may be added, it commonly blows with some violence.'

Mr. Kirwan, in an elborate paper on this subject (see Irish Transactions, vol. ii. p. 49. &c.) examines the different causes to which the phenomena of the barometer have been ascribed. He begins with the influence of different temperatures. It appears, he says, by observation, that a variation of the maps of the atmosphere is not a necessary consequence of an alteration of the temperature; for the mercury is often at the same height at different seasons, and at different places in the same season; and even when the height of the mercury changes simultaneously with the temperature, the change is often directly contrary, to that which the change of temperature would lead one to expect. Besides, great changes of temperature take place only in the lower atmosphere; but in the higher regions they are inconceivable. Any increment or decrement of the maps of the lower atmosphere that can be ascribed to a change of temperature, is too small to produce any considerable alteration in the height of the barometer; for in winter the height to which any considerable variation of temperature may be supposed to extend, scarcely exceeds 5000 feet, as we learn from the testimony of astronomers, and the height of the clouds; and indeed the winds that prevail on the surface of the earth, and which are the primary agents in producing a change of temperature, seldom reach higher, and in the more northern regions not so high. This cause, the effect of which is estimated by calculation, and compared with the actual variation, though not absolutely insufficient, on the supposition that the whole maps of the superfinecurrent column is increased by the accession of new air in proportion to the condensation, is nevertheless inadequate to the effect produced.

Mr. Kirwan next examines the efficacy of winds in producing the variations of the barometer; and these are such as reign in the lower regions of the atmosphere. If, according to Dr. Halley's theory, the rise of the barometer above its mean altitude were owing to the accumulation of air over the place of observation, occasioned by two contrary winds blowing towards that place, we should always have a calm when the wind is highest, but it is notorious, that the greatest mercuorial heights are accompanied by an easterly or northerly wind, as Halley himself has observed. Nor can that equality of barometrical heights, which takes place in very distant countries, where very different winds prevail, be explained by this hypothesis. This hypothesis attributes the defect of the mercury below its mean altitude to the rarefaction of the atmosphere over the place of observation, which rarefaction is owing to its exhibition by two contrary currents; for instance, over England, if it should blow a westerly wind on the German, and an easterly wind on the Irish sea. But Mr. Kirwan thinks, that a rarefaction in such circumstances from such a cause is impossible; for if such currents took place, the northern or southern air would flow in to maintain the equilibrium in the same proportion; or if this did not happen, and that four contrary currents took place, the higher air should descend, and cause a sensible cold, which yet is seldom observed in England, when the mercury is low; on the contrary, a warm south wind commonly prevails, to whose temperature nevertheless the rarefaction cannot be ascribed. Dr. Halley's explication of the defect of the mercury on high winds in

forms.
BAROMETER.

florms appears to Mr. Kirwan to be unsatisfactory. "The region of the earth," says Halley, "wherein those winds rage, not extending round the globe, the isazant air left behind and that on the sides cannot rush in fall enough to refote the evaporation made by so swift a current, so that not must be attenuated where the fald winds continue to blow."—"Add that the horizontal motion being fo quick may take off some part of the perpendicular prufure." This fall reafon seemed to acquire fome confirmation from an experiment made by Mr. Hawfbee; for having pafted a stream of air through a box in which the lower flank of a barometer was infected, he obferved the mercury to fall while the current paffed through the box; as also in another barometer which communicated with the box, wherein the current of air did not faw. Allowing this, the phenomenon is not sufficiently explained; for Mr. Kirwan obferves, that not only during the fform, but feveral hours, if not days, before it, the mercury defends confiderably, as Halley himfelf, and all who recommend the marine barometer, affert; otherwife this inftrument would be ufelefs. Mr. Cafwell obferves (Phil. Tranf. Abtr. vol. viii. p. 458), that two days before the great fform of January 1734-5, the mercury fell \( \frac{1}{2} \) of an inch below 28 inches. But if the fall were concomitant with the fform, Dr. Halley's reafons would not prove their connection. In order to a body's moving through air with fuch a velocity as to leave a vacuum behind it, there is a necefity that it fhould move at the rate of 11 or 1500 feet per fecond, as appears by the obfervations of Mr. Brice and many others. (See Phil. Tranf. for 1766, p. 266.) The inefficacy of the fecond reafon alleged by Dr. Halley has been clearly fhewn by M. de Luc; nor is the experiment of Mr. Hawfbee confufive, as it appears that part of the air already confined in the boxes was forced out by the blaff of air; and besides, Mr. Derham obferved that during the greatest vehemence of fform, the mercury rises instead of falling lower. (Phil. Tranf. Abtr. vol. iv. pt. 2 p. 77.) Mr. Kirwan made the fame obfervation on the 28th of February 1785, in London.

The third hypothifis is that of thofe who ascribe the variations of the barometer to the presence or abfence of vapours in the atmosphere; but Mr Kirwan infers, from a view of the nature of vapours, and the change they produce in the weight and elafcity of the atmosphere, that this theory does not fully account for the phenomenæ. If we fuppofe, fays he, the atmosphere perfectly dry, the barometer at 30 inches, and the thermometer at 65°, and then a column of it to be faturated with moisture, its elafcity being inereafed \( \frac{1}{2} \), which, according to his computation, would be the cafe, it will contain \( \frac{1}{2} \) of its volume lefs air than before faturafion, fince the inereaf of its elafcity arifes from the introduction of a new chufic fluid amounting to \( \frac{1}{2} \) of its bulk; and fince the weight of the whole volume was at fit equal to that of 30 inches of mercury, its weight will now be leffened by \( \frac{3}{4} \) of 30 inches, that is nearly 0.59 of an inch. But on the other hand, it gained \( \frac{1}{2} \) of its volume of vapour, and therefore its real lefs of weight will be the difference of the weight of \( \frac{3}{4} \) of air, and of \( \frac{3}{4} \) of vapour; but the weight of air is to that of vapour as 12 to 10, therefore the gain here is 0.49 of an inch, which deducted from 0.59 the lefs, leaves the lefs \( \frac{1}{2} \) of an inch. According to this, the variation which the barometer fhould undergo by the paffage of a column of air from abolute dryness to complete faturafion; a circumference which never takes place, as the atmosphere is never abolutely dry; and yet prevailed to heavy rains, we often obferve the barometer to fall 3, 4, or 5 tenths of an inch; a fall which, from the above calculation, cannot originate from the faturafion of the atmosphere with vapour. Nor is there any proportion between the fcent of mercury after heavy rains, and the weight of vapour condenfed; for in fuch cafes, the mercury frequently falls 3 or 4 tenths of an inch; and yet the heaviest rain seldom produces one cubic inch of water, and the weight of a cubic inch of water is not equal to that of even one tenth of a cubic inch of mercury.

Mr. Kirwan, having examined the cauaces to which the variable weight of the atmosphere and height of the barometer have been ufually referred, and controverted their deficiency, proceeds to explain that which alone seems to him adequate to the effects produced. This, in his opinion, is the accumulation of air over those parts of the globe in which the mercury exceeds its mean height; that is, the height fuited to its situation; and the diminution or subtraction of the natural quantity of air over those regions in which the mercury falls beneath its mean height. In order to trace the origin of this accumulation and diminution, this ingenious author confiders what may be called the natural state of the atmosphere, and how that state may be disturbed. The natural state of the atmosphere is that in which the barometer on the level of the fea would fland at 30 inches in fereine weather, conformably to the fifth obfervation above mentioned. For producing this state, the weight of the atmosphere must be every where equal at the furface of the fea; and as its weight proceeds from its density and height, in order to obtain this equality of weight, it fhould be lowest where its density is greatest, and highest where its density is leaft; and these extremes of density take place in the equatorial and polar regions. Hence it follows, that if the height of the mercury be 30 inches under the equator and under the poles, the atmosphere must be heigher under the equator and lower under the poles, with feveral intermediate gradations. (See Figure of the Atmosphere.) But though the equatorial air be lefs dense to a certain height than the polar, yet at certain greater heights it must be more dense; for the mercurial heights at the level of the sea being equal, the maflies of the coreresponding atmospheric columns must be equal. The fame obfervation applies to the extratropical columns with refpect to each other, where great differences of heat prevail. Hence it follows, that in the higher regions of the atmosphere, the denser equatorial air, not being supported by the collaterel extratropical columns, gradually flows to the north and south. If the influence of the northern and southern air to the equator by the trade winds kept pace with the influence of the superior air, some degree of equilibrium might still be maintained. But the trade winds move only at the rate of about 8 miles an hour; whereas without the tropics, or at least beyond latitude 30°, the currents of the upper atmosphere are incomparably more rapid. The mean heat of the whole space between latitude 60° and latitude 30° being only seven degrees lefs than the mean heat under the equator, the diference of density is not fo great as to caufe any rapid feparafion of the superior columns within that space; but from latitude 30° to latitude 60°, a much fmalter space, the mean annual heat over the oceans differs from that of latitude 30° by nearly fourteen degrees; and, therefore, the rapidity of the upper current towards the polar regions is much greater, and will occasion frequent interruptions, during which the weight of the air will be diminished. Hence, notwithstanding the high winds that frequently prevail between the tropics, the barometer inconvertibly and but seldom varies; whereas, without them, the variations are frequent and considerable, nearly in proportion to the distance from the equator; and thus
thus the second observation is sufficiently explained. During
the summer of the northern hemisphere, when it is win-
ter in the southern, the density of the equatorial air becomes
superior to that of the southern air at a much lower height
than that at which it becomes superior to the northern,
which is expanded by the presence of the sun in the northern
tropic; the exuberance will therefore be poured on the south-
ern region, and a smaller quantity will flow over the north-
ern; consequently the variations of the barometer are
smaller with us in the summer season. In winter, on the
contrary, the superior current is chiefly directed toward
the northern hemisphere, and hence the greatest mercurial
heights are found in this season; and thus the third observa-
tion is illustrated and confirmed. This accumulation takes place
where the columns of the inferior air are cold and short, and
as over that part of Asia beyond latitude 35°, and east of the
Caspian Sea to the Frozen ocean, and over the continent of
North America; and hence the barometer usually stands
higher in North America, and varies less than with us even
in Hudson's bay, latitude 59°. Accumulations are also
found in the southern parts of the old continent; and
when the rarefaction in the northern parts of Europe is fre-
cent and considerable, the southern air flows from these
tracts to restore the equilibrium, and while this current lasts,
the barometer must fall in the intermediate regions; so that
the descent of the mercury is never the effect of a
wotherly wind, but both it and this wind are the concomitant
effects of a rarefaction in the northern parts. On the other hand,
the mercury generally rises under a northerly or easterly wind,
because the superior atmosphere is accumulated chiefly in
those parts of our hemisphere from whence those winds blew,
and this accumulated air falls with them to the southern
regions. In the same manner, when the mercury falls before
a storm, both the storm and this fall proceed from a great
rarefaction of the air in the quarter towards which the storm
blows, and this rarefaction is occasioned by the diminution
or destruction of the superior atmosphere. As the superior
accumulation is derived to us chiefly from North America,
hence it is that the variations of the barometer generally
begin to the westward with us in Europe, and are thence
gradually propagated easterwards. In spring the current of
superior air begins to flow to the south, and in autumn to
return from it; hence the equinoctial storms and frequent
variations of the barometer in those seasons. The quantity of
equatorial air devolved on our hemisphere in different
years is variable, and so is the quantity confined in the
northern regions; and hence the mean barometrical height
is different in different years. In some years, the accumula-
tion reposing on the mountainous countries of the south of
Asia and Europe, and the northern part of Africa, is greater
than in other years; owing perhaps to a greater or earlier
fall of snow; when this is the case, the northern air is
lighter, and the southern colder than usual, and southerly winds
principally prevail, which in the northern parts must seem
to be comparatively warm; and hence, when the winter is re-
markably severe in the south of Europe and Asia, it is often
as remarkably mild in the northern parts, and the barometer
low. Although clouds and a disposition to rain frequently
follow the descent of the mercury, this defect is not the
immediate consequence of either clouds or rain; on the con-
trary, the mercury frequently rises during rain. But the
rarefaction of the atmosphere, which produces the defect
of the mercury, and which arises from the removal of the
superior accumulation, is favorable to the production of
clouds; as a heavy atmosphere, though it supports vapours
once formed, obstructs evaporation; when therefore its
weight is diminished, and evaporation increased, it soon be-
comes saturated in the higher regions, and clouds are formed.

But rain seems to arise from a subduction of the electrical
fluid, which, when the air abounds with vapours, is easily
carried to the earth. In serene and settled weather the
mercury is generally high, because the greatest disturbances
of the atmosphere are connected with its rarefied state, which
is commonly pretty distant when the superior accumulation
is considerable.

That the variations of the mercurial heights should be
greater at the level of the sea than at great elevations above
that level, is very natural. For supposing the mercury at
the level of the sea to stand at 30 inches, and at a certain
elevation above that level at 25 inches, then if the weight of
the atmosphere be diminished one hundredth part, the mer-
ccury at the level of the sea should fall one hundredth part
of 30 inches = 0.3 of an inch, but that on the elevation should
fall one hundredth of 25 inches, = 0.25 of an inch. But
it has been observed, that the variation on high mountains
is beyond all proportion smaller than on the level of the sea;
and this proceeds from a property which they seem to pos-
tess of condensing and accumulating the air incident upon
them in a greater degree than the air incident over plains is
condensed at equal heights; and hence when the barometer
on the plains falls, and that on the mountain also, it will be
found, after allowing for the difference of temperature, that
the fall is proportionably greater in the inferior than in the
superior barometer; and, on the contrary, if the mercury
ascends in both barometers, the ascent will be proportionally
greater in the superior than in the inferior. To this purpose
General Roy, found, on the 7th of August 1775, at 9 o'clock,
the correct height of a barometer at Caernarvon quay
30.075, and on the peak of Snowdon 26.405 inches; at 12
o'clock, that on the quay fell to 30.043, and that on the peak
26.405; the fall of the mercury on the plain was
therefore 0.032 of the whole, and the fall on the mountain
was only 0.045. On the other hand, at 2 o'clock, the barometer
on the quay rose to 30.054, while that on the peak rose to 26.415 inches correct height;
therefore that on the quay ascended only
1/75 of the whole, and that on the peak ascended
2/75 th part of its height. Yet as the defecents of the mercury beneath its mosit
usual mean height are much more frequent and considerable
than its ascents above it, the variations on mountains are
upon the whole proportionally smaller than at the surface
of the sea. For a more particular illustration of the theory
of Mr. Kirwan, and the collateral observations which he
deduced from it, we must refer to his paper, ubi supra. See
Atmosphere, and Aurora borealis. For other proposi-
tions of the weather, besides the variations of the barometer,
see Weather.

Another important purpose to which the variations of
the barometer have been applied, is the "measurement of alti-
ditudes." Whilst M. Pecule and M. Perrier were prosecute-
ing experiments for ascertaining the weight of the air by means
of the barometer, as early as the year 1668, they found that
the mercurial heights varied according to the situations,either
more elevated or more depressed, in which the barometer
was placed; and hence they concluded, that this instrument
might serve to determine how much one place was higher
than another. M. Pecule was not unacquainted with the
dilatability of the air, and he was therefore apprized of
one of the difficulties that have attended experiments of
this nature. The first person who estimated the height of
the atmosphere on these principles was Kepler; but hav-
ing, from ill-conducted experiments, very erroneous ideas of
the proportional specific gravities of mercury and air, he
rejected it at only two or three English miles. The Honorable
Mr. Boyle, deducing from experiments the proportion of the
specific gravity of mercury to that of air to be 1 to
14000.
1.050, and supposing the atmosphere to be equally dense, calculated its height to be twice as great as Kepler's measure or at least 35000 feet. But when the elasticity of the air was found to be in an inverse ratio of the space which it occupied, or that its condensation was proportional to the weight that compressed it, and of course that its dilatations were in the inverse proportion of the compressing weights, a property first discovered by Mr. Richard Townley, and demonstrated by Mr. Boyle, the height of the atmosphere was more accurately ascertained. Mr. Boyle's experiments to this purpose were published in 1661, in his "De Rebus et Experimentis," and exhibited the preceding year before the Royal Society. The law of the dilatation of the air was discovered also by M. Mariotte, and he published an account of his experiments for ascertaining it, in 1676, in his "Essai pour la Nature de l'Air," and "Tracté des Mouvements des Eaux." This law was generally admitted by philosophers, and it was confirmed by observation in all climates and at all times. To this purpose, M. Bouguer (Mem. Acad. Roy. Sc. 1753) gives us the result of the experiments made by himself and M. de la Coudamme in America; and he says that he found, without any exception, that the solidities of the same mass of air exactly corresponded to the ratio of the densities. M. Mariotte applied this general law to the investigation of the total height of the atmosphere. With this view, he collected many observations of the barometer made at small heights; and he was the first person who suggested the use of logarithms in estimating heights by the density of the mercury in the barometer, though the method had been generally ascribed to Dr. Halley, and Halley indeed framed tables of logarithms in the calculation of atmospheric altitudes. See Phil. Trans. No. 181, or Abstr., vol. ii. p. 1. Dr. Halley, assuming the specific gravity of the air to be 1, when the barometer stood at 36 inches, and in a mean state of heat and cold, to be 1.005, and that of mercury to water 131 to 1, (so that the weight of mercury to air is 10.806 to 1. or a cylinder of air of 10806 inches or 900 feet is equal to an inch of mercury,) inferred from these premises, that if the air were of equal density, like water, the whole atmosphere would be no more than 5.1 miles high; and that for an ascent of every 900 feet, the barometer would sink an inch. But the expansion of the air increasing in the same proportion as the incumbent weight of the atmosphere decreases, the upper parts of the air are much more rarefied than the lower, and every space corresponding to an inch of quicksilver is gradually enlarged, and therefore the barometer must be extended to a much greater height. As these expansions of the air are reciprocally as the heights of the mercury, they were be represented for any given mercurial height by means of the hyperbola and its auxiliary hyperbolic. Thus, in Plate XI. Pneumatics fig. 58 the rectangles ABC, AKG, ALD, &c. are equal; and consequently the sides CB, KG, LD, &c. are reciprocally as the sides AB, AK, AL, &c. (See HYPERBOLA.) If then AB, AK, AL, &c. be supposed equal to the heights of the mercury, or the corresponding pressures of the atmosphere, the lines CB, KG, LD, &c., answering to them, will be as the expansions of the air under those pressures, or the bulks which the same quantity of air will occupy; and if these expansions be taken infinitely numerous and infinitely small, their respective sums will give the spaces of air between the several heights of the barometer; i.e. the sum of all the lines between CB and KG, or the area CBKG, will be proportional to the distance of the interval intercepted between the levels of two places in the air, where the mercury would stand at the heights represented by the lines AB, AK; and, therefore, the spaces of the air answering to equal parts of mercury in the barometer are as the areas CBK, GKL, DLMF, &c.; but these areas are proportional to the logarithms of the numbers expressing the ratio of AK to AB, of AL to AK, of AM to AL, &c. Thus, by the common table of logarithms, the height of any place in the atmosphere, having any assigned height of the mercury, may very easily be found; for the line CB in the hyperbola, the areas of which represent the tabular logarithms, being 0.0414765, we shall have the following proportion: as 0.144765 is to the difference of the logarithms of 30 and of any lesser number, so is the space answering to an inch of mercury, if the air were equally pressed with 30 inches of mercury, and every where alike, or 900 feet, to the height of the barometer in the air, where it will stand at that lesser number of inches. By the converse of this proportion, the height of the mercury may be found corresponding to the given altitude of the place. It should be observed, that the number 0.0414765 is the mean between 0.0414732, the difference of the logarithms of 30 and 29; and 0.0014294, the difference of the logarithms of 30 and 31. The first difference represents the mean density of the air between the heights of 30 and 29 inches indicated by the barometer; and the second difference represents the mean density between 30 and 31; and the density of the air at 30 inches is the mean between these two densities. This calculation of Dr. Halley is founded on the supposition of equal and uniform gravity; but Sir Isaac Newton resolved the problem more generally (Proc. Phil. Trans. Nat. Math. Phys. § 52), and extended it to the true state of the case, where gravity is as the square of the distance inversely; and he showed, that when the distances from the earth's centre are in harmonic progression, the densities are in geometric progression. He also showed, in general, that by the same method, on any supposition of gravity, will produce a geometrical progression of the densities. See also Cotes's "Hydrometrical Lectures," and "Harmonics Menfurarium," and the article Height of the Atmosphere, and Atmospheric Logarithms in this dictionary. By these rules Dr. Halley calculated the following table:

Upon these suppositions it appears, that at the height of 41 miles, the air is so rarefied as to take up 3000 times the space it occupies here; and at 53 miles high it would be expanded...
BAROMETER.

expanded above 35,000 times: but it is probable, says Dr. Halley, that the utmost power of its spring cannot exert itself to fo great an extension, and that no part of the atmosphere reaches above 45 miles from the surface of the earth. However, it follows, from the principles above stated, that the air has a finite density at an infinite distance from the centre of the earth, or such as would be represented by an ordinate drawn through the centre. But at great distances its rarity would be so great, that its resistance would be insensible, though the retardation occasioned by it has been accumulated for ages. At the moderate distance of 500 miles, the rarity is so great that a cubic inch of common air expanded to that degree would occupy a sphere equal to the orbit of Jupiter; and the whole retardation caused by this planet, after five millions of years, would not exceed what would be occasioned by its meeting with one particle of matter weighing half a grain. Hence it may be reasonably inferred, that the visible universe is occupied by air, which, by its gravitation, will accumulate itself round every body in it, in a proportion depending on their respective quantities of matter; the larger bodies attracting more of it than the smaller ones, and thus forming an atmosphere about each.

Dr. Halley observes, that as the weight of the atmosphere is different at different times, its lower parts will be unequally pressed, and consequently its specific gravity will be also variable. This variation he partly attributes to the effect of heat and cold, and also to the influence of other causes; but he was of opinion, that the condensation and rarefaction, occasioned by cold and heat, and by the various mixtures of aequus and other vapours, compensate one another; for he says, that when the air is rarefied by heat, the vapours are more copiously raised; to that though the air, properly so called, be expanded and consequently becomes lighter, yet, its interferences being crowded with vapours and other matter specifically heavier, the weight of the compound may continue much the same.

He alleges an experiment of Mr. Caswell upon the summit of Snowdon hill to prove, that the first inches of mercury have their portions of air sufficiently near to what he has determined; for the height of the hill being nearly 1340 yards, Caswell found the mercury to have subsided to 25.6 inches, or 4 inches below the mean altitude of it at the level of the sea, and by his own calculation the space answering to 4 inches should be 1588 yards.

M. De Luc has given an historical and critical detail, in his "Recherches," vol. 1, p. 159, &c. of the attempts that have been made, and of the rules that have been proposed, by Maraldi, Scheuchzer, L. Caffini, D. Bernouilli, Horresbow; and Bouguer, as well as those of Pascal, Pierer, Mariotte, and Halley, for applying the motion of the mercury in the barometer to the measurement of altitudes. But the subject has been further pursued, and with a peculiar degree of accuracy, by De Luc himself, Sir Geo. Shuckburgh, and Gen. Roy, as we shall shew in the sequel of this article.

From the experiments of Boyle, Mariotte, Amontons, and others, it was inferred that the elasticity of the air is very nearly proportional to its density; and this principle, denominated the "Boylean law," was assumed by almost all writers on this subject. Thence experiments, however, were not very nice; nor were they extended to any great degrees of compresion, as the density of the air was not quadrupled in any of them. By the later and more accurate experiments of Sulzer (Mem. Brux. vol. 1.) Fontana (Quinta Phylaco-Math.), M. De Luc, sir George Shuckburgh, and Gen. Roy, it has been found that the elasticity of the air does not incaerse quite so fast as its density. From the Berlin experiments it appears, that the elasticity of the air of the temperature 55°, or the compressing force, increases so much more slowly than the density, that if the compressing force be doubled, the density will exceed the double by about a tenth part, &c. The law of this variation is expressed with tolerable exactness, by supposing that if D be the density of the air, and F the force compressing it, then

\[ D = F \times n \]

where \( n \) being a very small fraction, nearly 0.015. But new experiments are wanting to ascertain the law of this inequality with precision. Nevertheless, the general result has been, that the elasticity of rarefied air is very nearly proportional to its density; and the Boylean law may in general be allowed in cases of the greatest practical importance, or when the density does not much exceed or fall short of that of ordinary air. See Elasticity of the Air.

If we suppose the air to be of the temperature of 32° of Fahrenheit, and the mercury to stand in the barometer at 30 inches, we may allow \( \frac{1}{4} \)th of an inch for its descent if it be elevated 87 feet; and, accordingly, if the air were equally dense and heavy everywhere, the height of the atmosphere would be 30 x 10 x 87 feet, or about 5 miles. But as the air is an elastic fluid, whose density is always proportional to the compressing force, the altitude of the atmosphere will be much greater; and the method of calculating it by Dr. Halley and others, admits of a familiar illustration. Suppose then that a prismatic or cylindrical column of air, reaching to the top of the atmosphere, were divided into an infinite number of layers or strata of very small but equal thicknesses, and that every one of the particles of air that form these strata were of the same weight at all distances from the surface of the earth; it is plain, that the quantity of air in each stratum is as the density of the stratum, or as the compressing force, that is, the weight or quantity of matter of the superior and incumbent strata; consequently the quantity of air in each stratum is proportional to the superincumbent air; but the quantity in each stratum is the difference between the column on its bottom and on its top, and, therefore, these differences are proportional to the quantities of which they are the differences. But in a series of quantities proportional to their differences, the quantities themselves and their differences will be in continued geometrical progression: e.g. let \( a, b, c \) be three such quantities; then \( b : c :: a - b : b - c \); and, by alternation, \( b : a - b :: c : b - c \); and, by composition, \( b :: a + c \); a and \( b :: a + c \). Hence it appears that the densities of the strata decrease in a geometrical progression; that is, when the elevations above the centre or surface of the earth increase, or their depths under the top of the atmosphere decrease, in an arithmetical progression, the densities decrease in a geometrical progression. This principle may be applied to the purpose of measuring atmospheric altitudes in the manner of Dr. Halley above stated, or by means of that species of logarithmic curve, called from this application and use of it the "atmospherical logarithmic." (See Logarithmic Curve, and Atmospheric Logarithmic.) Let \( ARQ \) (fig. 99) represent the section of the earth by a plane passing through its centre \( O \), and let \( mOAm \) be a vertical line, and \( AE \), perpendicular to \( OA \), will be an horizontal line passing through \( A \), a point on the surface of the earth. Let \( AE \) represent the density of the air at \( A \); and let \( DH \), parallel to \( AE \), be taken in proportion to \( AE \), as the density at \( D \) is to the density at \( A \); and hence it is evident, that if a logarithmic curve \( EHN \) be drawn, having \( AN \) for its axis, and passing through the points \( E \) and \( H \), the density of the earth at any other point \( C \) of this vertical line, will be represented by \( CH \), the area of the curve in that point; because it is the property of this curve, that if portions \( AB, AC, AD \), of its axis be taken in arithmetical
BAROMETER.

With geometrical progression, the ordinates $AE, BF, CG, DH,$ will be in geometrical progression. It is another fundamental property of this curve, that if $EK$ or $HS$ touch the curve in $E$ or $H,$ the subtangent $AK$ or $DS$ is a constant quantity. Moreover, the infinitely extended area $MAEN$ equal to the rectangle $KAEL,$ of the ordinate and subtangent; and the area $MDNH$ equal to $SD \times DH,$ or to $KA \times DH,$ and, therefore, the area lying beyond any ordinate is proportional to that ordinate. These properties are analogous to the principal circumstances in the constitution of the atmosphere, on the supposition of equal gravity. The area $MCGN$ represents the whole quantity of aerial matter above $C,$ for $CG$ is the density at $C,$ and $CD$ is the thickness of the stratum between $C$ and $D,$ and, therefore, $CGHD$ will be as the quantity of air in it, and $O$ of all the others, and of their sums, or of the whole area $MCGN;$ and as each ordinate is proportional to the area above it, so each density, and the quantity of air in each stratum, is proportional to the quantity of air above it; and as the whole area $MAEN$ is equal to the rectangle $KAEL,$ so the whole air of variable density above $A$ might be contained in a column $KA,$ if, instead of being compressed by its own weight, it were without weight, and compressed by an external force equal to the preface of the air at the surface of the earth; and, in this case, its uniform density would be expressed by $AE,$ the measure of the density of the surface of the earth, and it would form what may be called the homogenous atmosphere. Hence it follows, that the height of this atmosphere is the subtangent of that curve, whose ordinates are as the densities of the air at different heights, on the supposition of equal gravity. In order to determine this subtangent, we may compare the densities of mercury and air; or, for a column of air of uniform density, reaching to the top of the homogenous atmosphere, counterbalances the mercury in the barometer. From the best experiments it is inferred, that when mercury and air are of the temperature of $32^\circ$ Fahrenheit, and the barometer stands at 50 inches, the mercury is nearly 10440 times denser than air; consequently the height of the homogenous atmosphere is 10440 x 30 inches = 313200 inches = 26100 feet = 8700 yards = 5 miles wanting 20 yards. Or we may compute this height by observing the variations of the barometer at known altitudes, thus; when the mercury and air are of the above temperature, and the barometer on the sea-shore stands at 30 inches, an ascent of 883 feet will cause it to fall to 29 inches. Moreover, in all logarithmic curves having equal ordinates, the portions of the axes intercepted between the corresponding pairs of ordinates, are proportional to the subtangents; and the subtangent of the curve belonging to our common tables is 0.4342945; and the difference of the logarithms of 30 and 29, which is the part of the axis intercepted between the ordinates 30 and 29, or 0.0147233: 0.4342945:: 883: 26046 feet = 8680 yards = 5 miles wanting 20 yards, differing from the former result 20 yards. This difference results from the difficulty of accurately ascertaining the respective densities of mercury and air, and also of duly estimating the elevation which causes a fall of one inch in the barometer. This investigation, however, proceeds upon the supposition of equal gravity; whereas it is well known, that the weight of a particle of air decreases as the square of its distance from the centre of the earth increases. In order, therefore, that a superior stratum may produce an equal preface at the surface of the earth, it must be denser, because a single particle of it gravitates less; consequently, the density at equal elevations must be greater than on the supposition of equal gravity, and the law of its diminution must be different.

Make $OD = OA : OA = O;\ OC : OA = OA : Oe;\ OB : OA = OA : Ob, \&c.:$ so that $Od, Oe, Ob, OA,$ may be reciprocals to $OD, OC, OB, OA,$ and through the points $A, B, C, D,$ make the perpendiculars $AE, bf, eg, db,$ proportional to the densities in $A, B, C, D,$ and let $CD$ be supposed exceedingly small, so that the density may be supposed uniform throughout the whole stratum. Then we shall have, $OD \times Od = OA^2 = OC \times Oe;$ and $Oe \times Od = OD : OC;$ and $Ob : Oe = Od : OD;$ and $Od : OD = OC,$ or $Oe : ed = OD : DC,$ and $ed : CD = OD : OD,$ or because $OC$ and $OD$ are ultimately in the ratio of equality, we have $cd : CD = Oc : OC = OA^2 : OC^2,$ and $cd = CD \times OA^2 \over OC,$ and $ed \times eg = CD \times eg = OA^2 \over OC;$ but $CD \times eg = OA^2 \over OC$ is as the preface at $C$ arising from the absolute weight of the stratum $CD;$ for this weight is as the bulk, as the density, and as the gravitation of each particle joined ly. But $CD$ expresses the bulk, $eg$ the density, and $OA^2 \over OC$ the gravitation of each particle. Consequently $cd \times eg$ is as the pressure on $G$ arising from the weight of the stratum $OC,$ but $cd \times eg$ is evidently the element of the curvilinear area $AMA,$ formed by the curve $EgNh,$ and the subtangents $AE,$ $bf,$ $eg,$ $ob,$ &c. &c. &c. Moreover, if $OA, Ob, Oc, Od,$ &c. be taken in arithmetical progression decreasing, their reciprocals $OA, OB, OC, OD, \&c.,$ will be in harmonical progression increasing (see Progression), because, from the nature of the logarithmic curve, when $OA, Ob, Oc, Od, \&c.,$ &c. &c. are in arithmetical progression, the ordinates $AE, bf, eg, db,$ &c., are in geometrical progression. Consequently, when $OA, Ob, OC, OD, \&c.,$ &c. &c. are in harmonical progression, the densities of the air at $A, B, C, D,$ &c. &c. are in geometrical progression; and thus the densities of the air at all elevations may be discovered. Thus, to find the density of the air at $K,$ the top of the homogenous atmosphere, make $OK = OA : OA = OL,$ and draw the ordinate $LT; LT$ is the density at $K.$

The correction for the diminished gravity of the air stated by professor Playfair (Edinb. Trans. vol. i. p. 118.) is a third proportional to the semidiameter of the earth, and the height as computed by the ordinary rule; and for different mountains, this correction is in the duplicate ratio of their heights. Dr. Horsey finds (Phil. Trans. vol. ixiv.), that in a height of 4 English miles, the diminution of density or volume from the accelerative force of gravity would be only 1/4th part of the whole, or about 4 feet; and this effect, being in the duplicate ratio of the heights, becomes at one mile high only three feet. Below the surface of the earth, it is but half the quantity; gravity within the earth being simply as the distance from the centre.
BAROMETER.

As the heights of the mercury in the barometer in all accessible elevations indicate the densities of the air at those elevations, the method of taking heights by this instrument may be illustrated in the following familiar manner.

It has already been observed, that if the mercury in the barometer stood at 30 inches, and the air and mercury be of the same temperature of 32° Fahrenheit, a column of air 87 feet thick has the same weight with a column of mercury \( \frac{4}{7} \) of an inch thick; and therefore if in ascending the mercury sinks to 29.6 inches, the interval of ascent is 87 feet. Suppose the barometer at a higher elevation to stand at 29.8 inches, and it be required to know the height to which the barometer has been carried. The flatness through which it has been raised, as the air is less compressed and rarer, must of course be thicker. The density of the first flatness may be called 300, eliminating the density by the number of tenths of an inch of mercury which its density is proportional to its density enables it to support. In the same manner the density of the second flatness must be 299. But when the weights are equal, the bulks are inversely as the densities; and when the bases of the flatness are equal, the bulks are as the thicknesses. In order therefore to obtain the thickness of the second flatness, lay 299:300::87:87.59, which denotes the thickness of the second flatness; and therefore the whole interval of the elevation of the barometer has been 174.29 feet. When the barometer at a higher elevation, say 29.8, lay 298:300::87:87.594; 29.6 298.795 the whole ascent. By this method may be computed the following table, in which the first column is the height of the mercury in the barometer, the second column is the thickness of the flatness, and the third column is the elevation above the preceding flatness, and the fourth column is the height above the first flatness.

</table>

In order to measure any elevation within the limits of this table, observe the barometer at the lower and at the upper flatness, and write down the corresponding elevations; subtract the one from the other, and the remainder is the height required. E. G. Suppose that at the lower flatness the mercurial height was 29.8, and that at the upper flatness it was 29.1.

29.1 - - - - 793.644

29.8 - - - - 174.291

619.353 the elevation required.

Without the aid of the table, let \( m \) represent the medium of the mercurial heights, and \( d \) their difference in tenths of an inch; then say, as \( m \) is to \( 300 \), so is \( 87d \) to the height required \( b \); or

\[
b = \frac{300 \times 87d}{m} = \frac{2610d}{m}.
\]

Thus in the preceding example, \( m \) is 29.45, and \( d = .7 \); and therefore,

\[
b = \frac{7 \times 2610}{2875.0} = 620.4,
\]

differing only one foot from the former value. The whole error of the elevation 883 feet, 4 inches, the extent of the table, estimated in either of these methods, is only \( \frac{4}{7} \) of an inch. It is needless however to recur to approximations, when the scientific and more accurate method first proposed by Dr. Halley is equally easy. Upon the supposition of equal gravity, as we have already shown, the densities of the air are as the ordinates of a logarithmic curve whose whole axis is the line of elevations. It has been also shown, that, in the true theory of gravity, if the distances from the centre of the earth increase in an harmonic progression, the densities will decrease in an arithmetical progression; but that the greatest elevation above the surface by but a few miles, this harmonic progression will nearly differ from an arithmetical one. Thus if \( AB, AC, AD \), are 1, 2, and 3 miles, the corresponding elevations \( AB, AC, AD \), will be nearly in an arithmetical progression also; for the earth's radius \( AC \) is nearly 4000 miles. Hence it follows that

\[
\frac{BC - AB}{BC} = \frac{1}{4000}
\]

which is a quantity altogether insignificant. We may therefore assume, that in all accessible places, the elevations increase in an arithmetical progression, while the densities decrease in a geometrical progression. Consequently the ordinates are proportional to the numbers which are taken to measure the densities, and the portions of the axis are proportional to the logarithms of those numbers. Hence it follows, that we may take such a scale for measuring the densities, that the logarithms of the numbers of this scale shall be the portions of the axis, that is, of the vertical line in feet, yards, fathoms, or any other measure; and we may, on the other hand, choose such a scale for measuring our elevations that the logarithms of our scale of densities shall be parts of this scale of elevation, and either of these scales may be found scientifically. For it is a known property of the logarithmic curves, that when the ordinates are the same, the intercepted portions of the abscissae are proportional to their subtangents. But the subtangent of the atmospheric logarithmic is known; it is the height of the homogeneous atmosphere in any measure we please, e.g., fathoms; and we find this height by comparing the gravities of air and mercury, when both are of some determined density.

Thus in the temperature of 32° Fahrenheit, when the barometer stands at 30 inches, it is known, as the result of many experiments, that mercury is 10423.068 times heavier than air; therefore the height of the counter-balancing column of homogeneous air will be 10423.068 times 30 inches, that is, 4342.945 English fathoms. It is also known that the subtangent of our common logarithmic tables, where 1 is the logarithm of the number 10, is 0.4342945. Consequently the number 0.4342945 is to the difference \( D \) of the logarithms of any two barometric heights as 4342.945 fathoms are to the fathoms \( F \) contained in the portion of the axis of the atmospheric logarithmic, which is intercepted between the ordinates equal to these barometrical heights; or that 0.4342945 : \( D \) :: 4342.945 : \( F \); but 0.4342945 is the tenth thousandth part of 4342.945, and therefore \( D \) is the tenth thousandth part of \( F \). Thus it accidentally happens, that the logarithms of the
BAROMETER.

densities measured by the inches of mercury which their
electricity supports in the barometer, are just the ten thou-
sandth parts of the fathoms contained in the corresponding
portions of the axis of the atmospheric logarithmic.
Therefore if we multiply our common logarithms by 100000,
they will express the fathoms of the axis of the atmospheric
logarithmic. Our logarithms contain the index or charac-
teristic, which is an integer, and a number of decimal places.
Let us then remove the integer place four figures to the
right hand, thus, the logarithm of 36 17 8 5 is multiply-
ted by 100000, and we obtain 36 17 8 5 130.

This reasoning may be very applied to practice, thus;
observe the heights of the mercury in the barometer and at
the upper and lower stations in inches and decimals; take
the logarithms of these, and subtract the one from the other;
and the difference between them, accounting the four first
decimal figures as integers in the manner now proposed, is
the difference of elevation in fathoms.

M. E.

Mercurial height at the lower station 29.8 - 1.4724163
At the upper station 24.1 - 1.4669830

Difference of logarithms x 10000 = 601 03 233 or 103 fathoms and 1.4732 of a fathom, which is 619.192
feet or 619 feet 2 inches, differing from the approximated
value before found about 8 inches. We have thus arrived
ourselves of the familiar and very intelligible illustration of
the method of measuring heights by means of the barometer
proposed and reduced to practice by Dr. Halley, given by
an ingenious anonymous writer in the "Encyclopaedia
Britannica," art. "Pneumatics." By this method it was
found that when the temperature of air and mercury was 32°
of Fahrenheit, the difference of the logarithms of the mer-
curial heights was precisely equal to the number of fathoms
of elevation; and it was verified upon the whole in practice,
by geometrical surveys and measurements.

The utility of it, however, was of very limited extent, and
it was seldom adopted, till M. De Luc first, and after him
Sir George Sackville and general Roy, introduced in con-
fidence of various observations and well-conducted ex-
periments such improvements and corrections as were found
to be necessary for expediting the practice of it and render-
ing the result of it accurate.

M. De Luc's apparatus of portable barometers, and their
annexed thermometers, with which he made his observations,
hath been already described. In the construction of his
barometers he guarded as much as possible against the im-
perfections and faults to which those of the common fort
are subject. The error arising from the repulsion of the
mercury by the glass tubes he remedied by substituting a
siphon barometer instead of the single upright tube, so that
the repulsion of the two legs of the siphon might counteract
itself. Another error resulting from air and moisture in the
barometrical tube he obviated by boiling the mercury in the
tube, and by other precautions. And he also shews how to
correct mistakes in the estimation of heights that are owing
to variations of the density of the mercury, and also of the
air, occasioned by heat and cold, by means of allowances
depending on two thermometers, one attached to the frame
of the barometer itself, and the other exposed to the open air
for measuring its degree of heat; and these thermometers are
to be noted both at the top and bottom of the hill. From
the use of this apparatus in a great variety of observations
he deduced a rule for calculating the heights of places,
which he verified by numerous experiments. Dr. Macler-
lyne and bishop Hogdly have reduced his rule from the
French to the English measure, and adapted it to the ther-

mometers of Fahrenheit's scale. M. De Luc (see Recherches,
&c. vol. i. p. 363—364) in the winter season, heated the
air of his room to as great a degree as possible, and observed
the rise of the barometer occasioned by the diminution of
its density or specific gravity by heat; and he also noted the
height of the thermometer, both before and after the room
was heated. Hence he deduced a rule that when the barometer
is at 27 French inches, which was the case in this
experiment, an increase of heat from freezing to that of
boiling water will raise the barometer 6 lines, or 1 th part
of the whole. But when the barometer is higher than 27
inches, this variation must be increased in the same proportion;
or it will be always 1 th part of the height of the barometer.
Consequently if the height be called H, the rise of the bar-
ometer corresponding to an increase of heat from freezing to
boiling water, will be \( \frac{B}{H} \); and as it will be less for a less

\[ \text{difference of heat, if the number of degrees marked on the} \]

thermometer between freezing and boiling water be called

\( K \), and the rise of the thermometer from any given point

be called \( H \), the corresponding rise of the barometer will be

\[ \frac{B}{K} \times \frac{H}{K} \] by the increase of heat from the given point

by the number of degrees \( H \). With a decrease of heat, \( H \)
would signify the degrees of decrease, and the barometer
would sink by \( \frac{B}{K} \times \frac{H}{K} \). The fixed temperature of
heat to which M. De Luc reduced his observations of the
barometer is \( \frac{1}{5} \) th of the interval from freezing to boiling
water above the former point; and if the thermometer
was higher than this degree, he subtracted \( \frac{B}{K} \times \frac{H}{K} \); if it was
lower, he added this quantity to the observed height of the
barometer; and he thus obtained its exact height, or such
as it would have been, if the density of its quicksilver had
been the same as answers to the fixed degree of temperature.

He thus corrected the height of both his barometers, that
at the bottom and that at the top of the hill, for the partic-
ular degree of heat, indicated by a thermometer attached
to the barometer at each station. These corrected heights
of the barometers were those which he used in his calcula-
tions. Then, scaling these two altitudes of the barometer
at the lower and at the upper stations, \( D \) and \( d \), and taking
\( \log. B \), and \( \log. b \) for the logarithms, taken out of the
common tables, and after subtracting the whole places of
figures after the index as integers, and the three remaining
figures as decimals, and putting \( C \) for the mean height of a
thermometer, exposed to the air at the top and bottom of the
hill, the freezing point being \( C \), and the point of boiling
water at \( 80 \), he found by his experiments that the height of the hill
would be given in French toises, when \( C = 163 \), by merely
taking the difference of the logarithms of the heights of
the barometer, or \( \log. B - \log. b \), and in any other
degree of heat, would be greater or less in proportion as the
rarity of the air was greater or less than in the fixed tempe-
ration; or greater or less, by \( \frac{1}{5} \) th part of the whole, for
every degree of the thermometer reckoned from the fixed
temperature \( 163 \); and consequently the height of the
place would be expressed generally in French toises by
this formula, viz. \( \log. B - \log. b + \log. B - \log. b \times \frac{C - 163}{215} = \log. B - \log. b \times 1 + \frac{C - 163}{215} \). The re-
duction of this formula to English measure and to the scale
of
of Fahrenheit's thermometer, is performed by the alronometer
royal (Phil. Trans. vol. lxiv. p. 96), in the following man-
er. The French foot is the barometer as 1.06575 to
1 (Phil. Trans. vol. lvii. p. 326); and the Fahrenheit's
point of freezing is 32, and that of boiling water 212, hav-
ing an interval of 180 degrees. But M. De Luc's point of
boiling water was marked when the barometer was at
27 French inches, that being its mean height at Geneva;
but our Englishmen mark the same point on Fahrenheit's
scale, when the barometer stands at 30 inches, which is
equal to 28 inches 1.8 lines French measure, or 14.8 lines
higher than M. De Luc's barometer. when he adjusted the
point of boiling water on his thermometer; and it is well
known, that the heat of boiling water varies with the
weight of the atmosphere. M. De Luc from his experi-
ments inferred, that an increase of one line in the height of
the barometer raises the mercury of the thermometer, placed
in boiling waters 11/24th part of the interval between the
freezing point and that of boiling water, though the rule
will not apply to large variations of the barometer occasion-
ated by very great heights above the earth's surface.
The change of the boiling point in Fahrenheit's scale corre-
sponding to a change of one line in the barometer, will be
1/52.5 degrees Fahrenheit's scale; and a thermometer, whose
point of boiling water was marked 212, when the barometer
stood at 30 English inches = 28 inches 1.8 lines French
measure, will, when the barometer descends to 27 French
inches, fix 2.2 degrees in boiling water, or to 309.8 or in
round numbers to 310 degrees, which is distant only 178
from the point of freezing. Hence it appears that an extent
of 83° of M. De Luc's thermometer corresponds to an
extent of 178 of our Fahrenheit's thermometer; and pur-
ifying for the degrees of this thermometer, corresponding
to C of M. De Luc's, we shall have C = F - 32 : 86 : 178,
and C = F - 32 x 1.8 which, substituted in the formula,
gives log. B = log. b x 1 + \frac{C-16^1}{215} = log. B
\begin{align*}
\text{log. } b & \times 1 + \frac{F-32 \times 1.8}{178} = \log. B - \log. b \\
\times 1 + \frac{F-32}{478.38} &= \log. B - \log. b + \frac{F-32}{478.38}
\end{align*}
log. B \times 1 + \frac{F-69.27}{478.38} \times 1.06575 =
log. B \times 1 + \frac{F-40}{478.38} =
\text{log. } b \times 1 + \frac{F-40}{478.38},
which expresses the height between the lower
flations in English fathoms.

In these expressions B and b denote heights of the barmo-

\[b = \pm \frac{D}{54K},\]

meter, at the lower and higher flations, corrected for the
difference of heat between a fixed temperature, viz. \(\frac{4}{5}b\) of
the interval between freezing and boiling water, and the
present heat, indicated by the thermometer attached to
the barometer at each nlation; but it will be sufficient, and
more convenient, to correct one barometer for the difference
of height of the two. Suppose then the upper barometer
is to be corrected, to reduce it to the temperature of the
lower one, and that b signifies the height of this baro-

\[b = \pm \frac{D}{54K},\]

metric, as observed and not corrected; the correction, from
what has been already said, if we call D the difference
of height of the thermometer attached to the barometer at
the two flations, e.g. at the top and bottom of the hill, will
be \(\frac{D}{54K}\), as the thermometer stands highest at the lower
or upper flation; and the upper barometer corrected, in
stead of b, will be

\[b = \pm \frac{D}{54K},\]

which, substituted in the
formula, gives log. B - log. b \frac{D}{54K} + \frac{F-40}{478.38}. But
the correction, on account of the difference of heat of the
barometer at the two flations, may be reduced to a more
easy expression, in which the variable quantity b, the height
of the upper barometer, shall not appear. The fluxion of a
logarithm is to the fluxion of its natural number as the
modulus of the system to the natural number; and 434.3
is the modulus of the common logarithms, when the four
places, next the index or characteristic, are taken as whole
numbers, instead of decimals, which is meant to be done in the
use of the preceding formula.

Consequently \(\frac{D}{54K}\) being very small with respect to
b, we shall have variation of log. b: variation of
\(b = \left(\frac{D}{54K}\right) \times 434.3: b\) very nearly, and hence variation of log.

\[b = \pm \frac{D}{54K} \times 434.3 = \frac{D}{54K} \times 4.52 D;\]

which, being substituted in the above formula, will give the
difference of height of the two flations, in English fathoms,
in a more convenient expression, viz.

\[\text{log. B - log. } b = \pm 0.452 D,\]

where the upper sign, +, is to be used, when the thermometer of the barometer is highest at
the lower flation, and the lower sign, −, is to be used
when the said thermometer is lowest at the lower flation.
When F, the height of Fahrenheit's thermometer, is less
than 40°, + \frac{F-40}{478.38}, becoming negative or subtrac-
tive, must be accordingly applied in the calculation. In
the foregoing formula, E denotes the observed altitude of
the barometer at the lower flation, and b that at the upper
flation; log. B and log. b denote their logarithms taken
out of the common tables, by affixing the four flint figures,
next following the index, as whole numbers, and con-
fidering the three remaining figures to the right hand, as
decimal, ; D signifies the difference of height of Fahren-
heit's thermometer, attached to the barometer at the top
and bottom of the hill; and F signifies the mean of the two
heights of Fahrenheit's thermometer, exposed freely for a
few minutes to the open air in the shade, at the top and
bottom of the hill.
The formula, for the measure of heights, may be adapted to thermometers of particular scales, for the convenience of calculation; but the scales will be different from those of M. De Luc. The thermometer attached to the barometer, will be best divided with the interval between freezing and boiling water, consisting of 81.4 degrees (180 x 452); the freezing point may be marked 0, and the point of boiling water will be 81.4; for then, if the difference of height of this thermometer, at the two latitudes, be called d, we shall have $d = \frac{F_{-40}}{81.4 x F_40}$, or $d = \frac{F_{-32}}{81.4 x F_{32}}$, the number of degrees expressed by d will show immediately the correction for the difference of heat of the two barometers. If the thermometer, designed to show the temperature of the air, be divided with the interval between freezing and boiling water $= 100$, and the freezing point be marked 0, and the boiling point $= 194$, and the heights of this thermometer, at the two latitudes, be called G and I, we shall have $F_{-40} = \frac{G + 1}{G+I} \times \frac{2}{5}$, or $F_{-32} = \frac{G + 1}{G+I} \times \frac{2}{5}$. For $F_{-40} = F_{-32} = 8$ is the height of Fahrenheit's thermometer, reckoned from eight degrees above freezing, and $440 : 600 :: 180 : 200 :: 8 : 9$, and the fraction $\frac{F_{-32} - 8}{449}$, increasing both the numerator and denominator in the ratio of 449 to 500, will become $\frac{F_{-32} - 8}{449} = \frac{500}{570} = \frac{G + 1}{G+I} \times \frac{2}{5}$, becausethe latter will be multiplied by $d = \frac{G + 1}{1000}$, which multiplied by 6, will give the height in English feet. It is to be observed, that $d + d$, or $-d$, is to be used, as the thermometer, attached to the barometer, is highest at the lower or upper station; and if G and I should happen to fall below 0 of the scale, or to be subtractive, they must be applied accordingly in the calculation.

The rules, expressed in the above formula, will be in common language as follows:

1. The rule adapted to Fahrenheit's thermometer is this. Take the difference of the tabular logarithms of the observed heights of the barometer at the two localities, considering the four first figures, exclusively of the index, as whole numbers, and the three remaining figures to the right as decimals, and subtract or add the 449th part of the difference of the alitude of the Fahrenheit's thermometer, attached to the barometer at the two latitudes, according as it was highest at the lower or upper station; thus you will have the height of the upper station above the lower in English fathoms nearly. This is to be corrected in the following manner: say, as 449 is to the difference of the mean altitude of Fahrenheit's thermometer, exposed to the air at the two stations, from $40^9$, so is the height of the upper station found nearly to the correction of the same: which, added or subtracted, according as the mean altitude of Fahrenheit's thermometer was higher or lower than $40^9$, will give the true height of the upper station above the lower, in English fathoms, and multiplied by $d$ in English feet.

2. The rule adapted to two thermometers of particular scales is as follows. Take the difference of the tabular logarithms of the observed heights of the barometer, at the two stations, considering the four first figures, exclusively of the index, as whole numbers, and the three remaining figures to the right as decimals; and subtract or add the difference of the alitudes of the thermometers of a particular scale, attached to the barometer, at the two stations, according as it was highest at the lower or upper station, and you will have the height of the upper station above the lower one in English fathoms nearly; subject to the following correction: say, as $100^9$ is to the sum of the altitudes of the thermometers of a particular scale, exposed to the air at both stations, so is the height of the upper station above the lower, found nearly, to the correction of the same: which, added or subtracted, according as the sum of the altitudes of the thermometers, exposed to the air, is positive or negative, will give the true height of the upper station above the lower in English fathoms, and multiplied by $d$, in English feet. Dr. Horfley, the present Bishop of St. Alban, has given a comparison of M. De Luc's rules with theory, reduced them to English measures of length, and adapted them to Fahrenheit's scale of the thermometer, and added tables and presents for expediting the practical application of them in the Phil. Traut. vol. ii. p. 213. Sec. Atmospheric Logarithmic and Fixed Points of Thermometers.

The scene of M. De Luc's first observations was mount Saleve, near Geneva. Here he selected 15 stations at different elevations; and the following table abridged and abridged from his minute details (Recherches, &c. vol. ii. p. 213, &c.) shews the result of his operations:

The latest and most accurate experiments and observations relating to this subject, are those of Sir George Shuckburgh, and General Roy. In order to render the method of measuring altitudes by the barometer more exact, it is necessary to ascertain by appropriate experiments the expansion of mercury by any increase of temperature, and also the expansion of air by the same, or by any change of temperature; and also the variations to which its elasticity is subject. It has been already stated, that M. De Luc estimates the expansion of quicksilver, between the temperatures of melting ice and boiling water, to be exactly 6 French lines, or 538.75 decimal parts of an English inch. But he suppose the barometer to stand at 37 Fr. inches, or 28.7525 Eng. inches; whereas, if it had stood at 30 inches, it would have been.
been 555555, because the expansion is proportional to the length of the column. It has also been shown, that M. De Luc's boiling point is 22.2° lower than that of English thermometers, reducing it to 209.8 Fahrenheit, and making the interval between freezing and boiling only 177.8 degrees. Hence the expansion 555555 must be augmented in the proportion of 177.8 to 180, which gives for the total 5624507 or 502453, on a difference of temperature of 180°. Thus the expansion for each degree, supposing it to be arithmetical, or uniformly the same in all parts of the scale, will be .00012461. But from information communicated by M. De Luc to general Roy, it appears that the difference of temperature in his experiments amounted to about 31° of Reanun, or 72° of Fahrenheit, above freezing; and therefore .00012461 x 72 = 2.25 nearly will denote the rate of expansion, from which he deduced that for 180°.

The experiments of general Roy for ascertaining the expansion of mercury are minutely detailed in the Phil. Trans. vol. lxvi. p. 359--682. He exposed 30 inches of mercury, contained in a barometer by the atmosphere, in a nice apparatus, by which it could be made of one uniform temperature, through its whole length, and he noted the expansion of it in decimals of an inch. The result appears in the following table; of which the first column expresses the temperature by Fahrenheit's thermometer, the second column expresses the bulk of the mercury in consequence of its expansion; and the third column shows the expansion of one inch of mercury for an increase of one degree in the adjoining temperatures.

</table>

By this table the observed height of the mercury may be reduced to what it would have been if it were of the temperature 32°. Suppose that the mercurial height is observed to be 29.2, and that the temperature of the mercury is 72°; lay 30.1302 : 30 :: 29.2 : 29.0758, which would be the true measure of the density of the air of the standard temperature. In order to obtain the exact temperature of the mercury, the observation should be made by a thermometer attached to the frame of the barometer, that it may warm and cool along with it. This, however, may be done, with sufficient accuracy, without a table; as the expansion of an inch of mercury for one degree decreases very nearly 30a.3rd part in each succeeding degree. If, therefore, we take from the expansion at 32° its thousandth part for each degree of any range above it, we obtain a mean rate of expansion for that range. When the observed temperature of the mercury is below 32°, this correction must be added, in order to obtain the mean expansion. This rule will be more exact if we suppose the expansion at 32° to be .0001127, as in the table. Then, by multiplying the mercurial height by this expansion, we obtain the correction to be subtracted or added as the temperature of the mercury was above or below 32°. Thus, in the former example of 72°, take 49, the excess of 72° above 32°, from 0.0001127, and we have 0.0001087. Multiply this by 40, and we have the whole expansion of one inch of mercury =0.004348. Multiply the inches of mercurial height, viz. 20.2 by this expansion, and we have for the correction 0.1266; which, subtracted from the observed height, leaves 29.07304, differing from the exact quantity less than the thousandth part of an inch. This correction may be made by another process, still more simple; or by multiplying the observed height of the mercury by the difference of its temperature from 32°, and cutting off four cyphers before the decimals of the mercurial height: and this method will seldom err one hundredth of an inch. Having thus corrected the observed mercurial heights by reducing them to what they would have been if the mercury had been of the standard temperature, the logarithms of the corrected heights are taken; and their difference, multiplied by 10000, will give the difference of elevations, in English fathoms. Another method of applying this correction, more expeditious, and not less accurate is as follows. As the difference of the logarithms of the mercurial heights is the measure of the ratio of those heights, so likewise the difference of the logarithms of the observed and corrected heights at any inclination is the measure of the ratio of those heights; and, therefore, this latter difference of the logarithms is the measure of the correction of this ratio. But the observed height is to the corrected height as 1 to 10000.102; and the logarithm of this ratio, or the difference of the logarithms of 1 and 10000102, is 0.0000444. This is the correction for each degree by which the temperature of the mercury differs from 32. Therefore multiply 0.0000444 by the difference of the mercurial temperatures from 32, and the products will be the corrections of the respective logarithms. The following method of applying the logarithmic correction is more easy than the former. The correction will only be necessary, when the temperatures at the two stations are different, and it will be proportional to this difference. Therefore, if the difference of the mercurial temperatures be multiplied by 0.0000444, the product will be the correction required on the difference of the logarithms of the mercurial heights. Moreover, since the difference of the logarithms of the mercurial heights are also differences of elevation in English fathoms, it follows, that the correction is also a difference of elevation in English fathoms; or that the correction for one degree of difference of mercurial temperature is 3.858 feet at a fathom = 32 inches = 2 feet 8 inches. This correction of 2.8 for every degree of difference of temperature must be subtracted.

BAROMETER.

Sir George Shuckburgh, in his barometrical observations, reckoned the equation for the expansion of mercury
\[ \text{Barometer} = 0.245 \text{ of an inch for every degree of Fahrenheit's thermometer.} \]
By observations still more accurate, it has been found, that the temperature at which the difference of
the logarithms gives the height in English fathoms is 32°, and that the correction at other temperatures is 0.0243 of
that difference for every degree of the thermometer. The manner of estimating the temperature of the air, adopted
in all these observations, was the same; an arithmetical mean
was taken between the heights of the thermometer, at the upper and lower flations, and was supposed to be uniformly
diffused through the column of air intercepted between them.

M. De Luc, however, was apprized of the inaccuracy of this hypothesis; and general Ray, too, has observed, that
one of the chief causes of error in barometrical computation
proceeds from the mode of estimating the temperature of the column of air from that of its extremes, which
must be fault in proportion as the height and difference of
temperature are great. Indeed it seldom or never happens,
that any particular stratum of air is uniformly of the same
temperature. It is commonly much colder above; and it is
also of different confections. Below it is warm, loaded
with vapour, and very expansible; above it is cold, much
drier, and less expansible both by its dryness and its rarity.

Currents of wind, also, are often disposed in strata, which
retain their places for a considerable time; and as they
come from different regions, are of different temperatures
and constitutions. It is either certain that the whole
intermediate stratum expands alike, nor that the expansion
is equal in the different intermediate temperatures. Rare
air expands less than that which is denser; and there is a
particular elevation at which the general expansion, instead
of diminishing the density of the air, increases it by the
superior expansion of that which is below. But no general
rule has been established by which we can obtain a more
accurate correction than by taking the expansion for the
mean temperature.

Sir George Shuckburgh has exhibited the result of
several experiments on the expansion of air by a change of
temperature in the following table, where is seen the in-
crease in bulk of 1000 parts of air of the temperature of
freezing and pressure of 30 inches, by an addition of 1
degree of heat in Fahrenheit's thermometer.

Mean from the first manometer 2.44.

Mean from the second manometer 2.42.

The mean of these two sorts of observations, made with
different instruments, is 2.43, viz. 1000 parts of the air at
freezing become by expansion from 1° of heat equal 1002.43
parts or 1002.385 parts with the standard temperature 30°.7.

Whereas
BAROMETER.

Whereas M. De Luce's experiments reduced, give this quantity equal 1002.23 parts. General Roy compared a mercurial and an air thermometer, each of which was graduated arithmetically; that is, the units of the scales were equal bulks of mercury, and equal bulks of air. Their progress is exhibited in the following table.

As equal increments of heat produce equal increments in the bulk of mercury, the differences of temperature are expressed by the second column, and may be considered as equal; and the numbers of the third column express the same temperatures with those of the first. They directly express the bulks of the air, and the numbers of the fourth column express the differences of these bulks. These are evidently unequal, and they show that common air expands more of all when the temperature is 62 more nearly. In order to determine what was the actual increase of bulk by some known increase of heat, general Roy took a tube of a narrow bore, with a ball at one end. He measured the capacity of both the ball and the tube, and divided the tube into equal spaces, bearing a determined proportion to the capacity of the ball. This apparatus was placed in a long cylinder filled with frigid mixtures or with water, which might be uniformly heated to the boiling temperature, and it was accompanied by a nice thermometer. The expansion of the air was measured by means of a column of mercury, which rose or sunk in the tube. The tube being of a small bore, the mercury did not drop out of it; and the bore being chosen as equal as possible, this column remained of an uniform length, whatever part of the tube it chanced to occupy. By this contrivance he was able to examine the expansibility of air of various densities. When the column of mercury contained only a single drop or two, the air was nearly of the density of the external air. If he wished to examine the expansion of air twice or thrice as dense, he used a column of 50 or 60 inches in length; and to examine the expansion of air that is rarer than the external air, he placed the tube with the ball uppermost; the open end passing through a hole in the bottom of the vessel containing the mixtures or water. By this position the column of mercury was hanging in the tubes supported by the pre-

In order to have a mean expansion for any particular range, as between 12° and 92°, which is the most likely to comprehend all the geodetical observations, we need only take the difference of the bulks 20.638 and 22.106 = 195.666, and divide this by the interval of temperature, 80°, and we obtain 2.4466, or 2.45, for the mean expansion for 1°. This table, which in its present form shews the expansibility of air of the temperature 6°, may be easily adapted to explain the difference of air of the standard temperature 32°, by laying (for 212°), 109.718: 484.201: 1000: 134.89: and so of the rest. Thus the following table is constructed.

Hence we have the mean expansion of 1000 parts of air between 12° and 92° = 2.29.

The following table shews the result of general Roy's experiments on air much exceeding the common density. The first column contains the densities measured in the inches of mercury which they will support when they are of the temperature 72°; the second column shews the expansion of 1000 parts of such air by being heated from 0 to 212°; and the third column is the mean expansion of 1°.

General Roy made many experiments on air much below the common density, and he found, in general, that their expansibility by heat was analogous to that of air of ordinary density, being greatest at the temperature of 6°. He also found, that its expansibility with heat decreased with its density; but he was not able to ascertain the law of graduation. When reduced to about 4th of the density of common air, its expansion was as follows.

Mean expansion 0.786

From the experiments to which we have above referred it appears, that the expansibility of air is greatest when the air is about its ordinary density, and that in small densities it is greatly diminished. But it appears upon the whole, that there is little difference in the actual expansion or elastic force of air, prefined with an atmosphere or one third part; yet, when it is rendered extremely rare, its elasticity is wonderfully diminished. It should seem, indeed, that the elastic force of common air is greater than when its density is considerably augmented or diminished by an addition to or subtraction from the weight with which it is loaded; and this observed difference contradicts the experience of Boyle, Mariotte, &c. It also appears that the law of compression is altered; for in the preceding specimen of the rare air half of the whole expansion happens about the temperature of 99°, but in air of ordinary density at 105°. As this is the case, the experiments of M. Amontons, in the Memoirs of the Academy at Paris for 1702, &c. are not inconsistent with those of general Roy. Amontons found that whatever was the density of the air, at least in cafes where it was much denser than common air, the change of 180° of temperature increased its elasticity in the same proportion; for he found, that the column of mercury which it supported, when the temperature 50, was increased 1/4 at the temperature 212°; and hence he fairly inferred, that its expansibility was increased in the same proportion; but this is by no means the cafe, unless we are certain that in every temperature the elasticity is proportional to the density; which still remains to be decided.

From another class of experiments made by general Roy, we learn, that the elastic force of moist air is greatly superior to that of dry air; and that a very uniform increasing progression is perceived to take place from the zero of Fahrenheit, as far as 152° or 172°, and even to the boiling point. From the mean result of these experiments, which are arranged in a table, it appears, that the expansion of air, however moist, having that moisture condensed or separated from it by cold, differs not sensibly from that of dry air. Thus the rate for 32° below freezing 2.22799 is nearly the same as in dry air; but as soon as the moisture begins to dissolve and mix with the air, by the addition of 20° of heat, the difference is perceptible; for instead of 2.45975, the rate for 20° above 32° in dry air, we have 2.588 for that which is moist. In the next college of 20°, the rate for dry air is 2.588; whereas that for moist air the progression goes on continually increasing, fo as to give 7.86854 for the mean rate on each degree of the 21°, which is near 3 times the expansion of dry air. And, finally, the rate for the 20° between 192° and 212° is twice and one-half the mean rate, and about nine times that which corresponds to the zero of the scale, but the comparison being drawn from the mean of some particular experiments, as being probably nearest the truth, the total expansion of moist will be more than four times that of dry air; and the rate for the temperature at boiling will be nearly 15 times that which corresponds to the zero of Fahrenheit. This circumstance will probably account for the deviations from the rules established for determining heights by the barometer, which take place in the provinces of Quito in Peru, and at Sintzebergen, within 10 degrees of the pole. In the former situation, which is at a great elevation above the level of the ocean, the heights obtained by these rules fall considerably short of the real heights; and at the latter place they considerably exceed them. Near the surface of the earth there is a greater degree of humidity and heat in the air than there is in the higher regions of the atmosphere; and the elasticity or expansion of the lowermost section of
BAROMETER.

1. Subtract the logarithm of the barometrical height at the upper station from the logarithm of that at the lower, and count the index and four first decimal figures of the remainder as fathoms, the rest as a decimal fraction. Call this the elevation.

2. Note the different temperatures of the mercury at the two stations, and the mean temperature. Multiply the logarithmic expansion corresponding to this mean temperature (in Table II) by the difference of the two temperatures, and subtract the product from the elevation, if the barometer has been colder at the upper station; otherwise, add it. Call the difference, or the sum, the approximated elevation.

3. Note the difference of the temperatures of the air at the two stations by a detached thermometer, and also the mean temperature and its difference from 32°. Multiply this difference by the expansion of air for the mean temperature, and multiply the approximated elevation by 1 ± this product according as the air is above or below 32°. The product is the correct elevation in fathoms and decimals.

Example.

Suppose that the mercury in the barometer at the lower station was at 29.4 inches, that its temperature was 50°, and the temperature of the air 45°; and let the height of the mercury at the upper station be 25.10 inches, its temperature 46, and the temperature of the air 39. Here we have

Sir
BAROMETZ, in Botany. See Polypodium.

BARON, a person who holds a barony.

Baron is a term which origin and primary import are much contended. Some will have it originally denote a man, 

var: some a hero, or valiant man; some a libertinus, or freeman; some a great, or rich man; some a valet, or base-man.

Menage derives it from the Latin baro, which we find used in the pure age of that language for air, a wind, or a violent man; whence, according to this author, it was that those placed next to the king in battles were called barones, and that the bravest men in the army were the barones. Occasionally rewarded the bravery and fidelity of those about them with fees, the word came to be used for any noble person who holds a fee immediately of the king, -J-fidore, and after him Camden, take the word in its original sense, to signify a mercenary soldier. Mefliers of the Port Royal derive it from baro, a wind, or a violent man, or authority. Cicero uses the word baro, for a stupid brutal man; and the old Germans make mention of buffeting a baron, i.e. a valiant; as the Italians still use the word barone, to signify a beggar.

M. de Marea derives baron from the German bar, man, or freeman; others derive it from the old Gaulish, Celtic, and Hebrew language. But the most probable opinion is, that it comes from the Spanish varo, a float, noble person; whence wives come to call their husbands, and princes their tenants, barons. In the Saxon law, as well as the laws of the Lombards, the word baron signifies a man in the general, and the old glossary of Philomelates translates baron by varo, man.

BARON, the title of a lord or peer of parliament, being the next degree below that of a viscount. A baron hath the title of Right Honourable, and all acts and proceedings is styled Moi t baron. The parliamentary robe of a baron is scarlet cloth, lined with white fustian, having on the right side two guards of Minerva, or ermine, which signifies his degree. The coronet of a baron is a rim of gold, having thereon six pearls; this coronet was granted them by Charles II. by patent bearing date 6th July 1661, before which they wore a crimson cap turned up with ermine, and on the top a tassel of gold, now called a baron's cap. A baron may appoint three chaplains. In ancient records, the word barons included all the nobility of England, because regularly all noblemen were barons.

The word baron of itself originally did not, more than peer, signify an immediate vassal of the king; for earls patriatic had their barons, that is, their immediate tenants; and in old records, the citizens of London are styled barons, and so are the representatives of the five ports called to this day. Baron, therefore, at first signified only the immediate tenant of that superior, whose baron he is said to be; but by length of time it became restrained to those who, properly and exactly speaking, were barones regis & norm. and even not to all of these, but to such only as had manors and courts therein; for though, by the principles of the feudal constitution, every immediate military tenant of the

This rule may be expressed by the following formula, which is simple and easily remembered; a being the difference between 35° and the mean temperature of the air, d the difference of barometric heights in tenths of an inch, m the mean barometric height, b the difference between the mercurial temperatures, and E the correct elevation. 

\[ E = \sqrt{m^2 + 0.21^2} \pm \frac{d}{\sqrt{2}} \]

BAROMETERS, Animal. See Antemone.

BAROMETZ, in Botany. See Polypodium.
the crown, however small his holding, was obliged to affit the king with his advice, and entitled likewise to give or refuse his assent to any new law or sedition, that is, to attend in parliament; this attendance was too heavy and burthenome upon such as had only one or two knight's fees, and could not be compiled with without their ruin. Hence arose the distinction between tenants by knight's service and tenants by knight's fee in the reign of Henry I. The former were feudal tenants of the king, as lord estats, and qualified them with the onus of attendance in parliament, and who were therefore entitled to be summoned; the quantum of this estate was equally thirteen knight's fees, and one out of ten, or, as the case of a count or earl was two & four; that is, as a knight's fee was then reckoned at £1 per annum, the baron's revenue was 40 marks, or £10. 4d.

Such was the nature of all the baronies of England, for about two hundred years after the conquest; and they are called baronies by tenure, because the dignity and privileges were annexed to the lands they held, and if these were alienated with the conquest of the king (for without that they could not), the barony went over to the alien. Of these Matthew Paris tells us there were 250 in the time of Henry III.; and whilst they flouid freely on this footing, it was not in the king's power to increase the number of the baronies; though of barons perhaps he might; for as William the Conqueror was obliged to gratify several of his great officers, according to the number of men they brought, with two or more baronies, whenever these fell into the hands of the crown by echeate, either for want of heirs, or by forfeit, it was in the king's power, and it was his interest, to divide them into separate hands. The same thing likewise happened, when, by an intermarriage with an heiress, more baronies than one came into the hands of a nobleman, and echeated to the crown. But the number of these feudal baronies could not, strictly or properly speaking, be increased by the king; for they could be created only out of lands, and there were no lands vacant to create new ones out of, for the king's demesnes were in those days unalienable. However we find, at the end of Henry the Third's reign, and even in John's, that the number of baronies were actually increased; and a distinction made between the barones majoris and minores.

The majoris were those who flourished on the old footing of William, and had lands sufficient in law, namely, the number of the knight's fees requisite. The minores were such as held by part of a barony; and when an old barony descended to, and was divided among fitters, in which case, when the husband of the fitter whom the king pleased to name was the baron of parliament, or else was newly carved out of the old baronies that had fallen in by echeate; as supposing the king had granted six knight's fees of an old barony to one to hold with all the burthen and to the service of an entire barony, and the remaining seven and one-third to another on the same terms. But the attendance of these minor barons also at length became too burthome for their circumstances, and many of them were glad to be excused. The king took then the power of pawning by such as he thought unable, by not letting them writs of summons; and John extended his prerogative even to omit summoning such of the majoris as he imagined were inclined to oppose him: this however at length he was obliged to give up; for in his magna charta it is said, "et habendum commune consilium regni faciems fummoni ecclesiorum episcoporum, abbatis, comites, & barones regni regis, filiati per litteras nostras."

The barones majoris were there fully and plainly distinguished from the minores; and we apprehend it will not be doubted they were such as had the full complement of knight's fees that made up an ancient barony; and accordingly we find, in 1255, when Henry the Third had neglected summoning some of them, the others refusing to enter on any business, "quis omnes tunc temporis non fuerunt, juxta tenorem magnae chartae, vocari; et idem, fine paribus suis tunc absentibus, nulnum voluerunt tunc reponendum dare, vel auxilium concedere, vel prelare." No king since ever omitted to summon all the greater nobility, until Charles the Sixth was prevailed upon to forbid the sending a writ to the earl of Bristol, by Buckingham, who was afraid of being accused by that nobleman; but on the application of the house of lords, and their adjourning themselves from day to day and doing no business, the writ at last was issued.

In the reign of Henry the Third also, the king's prerogative of summoning or omitting the lesser barons was likewise averted by an act of parliament since lost, as we find by these words from history: "Ille enim reg(uis) He(hnricus Tertius) post magnas perturbationes & enormes vexationes inter ipsum regem, Simonem de Montforti & alios barones, motas & spatias flatuit et ordinavit, quod omnes illi comites & barones regni Angliae, quibus ipsis dignitatis specie brevia dirigere, verecent ad parliamentum, & non ait, nili forte dominus rex ad illa brevia illis dirigere voluerit: &" and from henceforth no nobleman could fit in parliament without a writ. But there was this difference between the greater and the lesser barons, that the former had a right to their writ &c. &c. to the latter it was a matter of favour; but when summoned, they being lesser barons, had the same rights with the red, though sitting not by any inherent title, but by virtue of the writ. The other lesser barons, who were generally omitted to be summoned, by degrees mixed with the other king's tenants in capite, and were thenceforth represented by the knights of the shires. But these baronies by tenure being long since worn out among the laity, it is proper to proceed to the two ways now in being of creating peers; by writ, and by letters patent. It was lord Coke's opinion, and in this he has been followed ever since, that a writ to any man, baron or no baron, to sit in parliament, if once he hath taken his seat in pursuance thereof, gains a barony to him and the heirs of his body; and though the law, principally on the authority of that great lawyer, is now fo settled, certainly it is comparatively but a novel opinion, and very ill to be supported by reason. The words of the writ are: " Rex tali felutem quia de adiuvamento & afferendo confili notri, pro quibusdam ardus & urgentibus negotiis ilium & defensionem rei notri Angliae concernentibus, quod ad parliamentum nostrum apud Westminstera, tali die talis menis proximo futuro teneri ordinarianus & ibidem vocatus, ac cum prelati magnatibus & proceribus dicti regni notri, colloquium habeare & tractari; vobis in fide & fideantia quibus nobis tenenimi firmer injuniendo mandamus, quod considerabimus dictam negotiorum arduitate & periculis imminentiis, celfante exculsione quacunque, dictis die & loco perfonsalter interitus nobiscum, ac cum prelati magnatibus & proceribus super dictis negotiis tractari, vel communique coniurium impensuri, & hoc scit nos, & honorum nostrum, ac expeditiones negotiorum predictorum diligius, nullians omnitrans."
That this writ must be obeyed there is no doubt, for every subject is by his allegiance obliged to assist the king with faithful counsel; but what right the party summoned acquired thereby, is the question. The words are not only personal to him, but directed likewise to a particular place and time; and, accordingly, in ancient times we had many persons summoned to one parliament, omitted in the next, and summoned perhaps to the third. There is not a word therein that hints at giving the right to an heir; and what reason can be assigned why a man by this writ should gain an estate of inheritance in a peerage, when in letters patent it is admitted that he gains only an estate for life, without the word heirs. That anciently there was no such notion appears from the summons to parliament, where frequently we find the grandfather summoned, the father killed by, and the grandson afterwards summoned; nay, in the rolls there are instances of ninety-eight persons being summoned a single time only, and neither themselves nor any of their posterity ever taken notice of afterwards. Or if we were to allow that this writ created an inheritance, what reason can be given why it should be an estate tail only, and be confined to the heirs of the body, and not, as all other new inheritances created generally, go to the collateral heirs?

But in order to discover plainly what privileges persons so called by writ had or could obtain in those times, it will be proper to distinguish them into three kinds of persons: first, then, they were either some of the \textit{minores barones by tenure}, and these, when called, had certainly all the privileges of the greater, or else they were not barons at all, but plain knights or gentlemen; and in respect to the crown, it is plain they had a right to deliberate, debate, and advise; but the better opinion is, they had no right to vote, but were such as the judges are at present, for it is absurd to suppose that in those times, when the commons were low and inconsiderable, and the barons were more powerful than the crown, that the latter should suffer their resolutions to be over-ruled at the pleasure of the king, by calling in such numbers as we find he often did, which must have been the case if all he had summoned had votes. But these two kinds of persons gained by their writ or sitting in consequence of it, originally, no farther right than to be present at that time. However, by many of these persons and their heirs having been constantly summoned, especially since Henry the Seventh's reign, and the ancient practice of omitting any who had been very frequently going into dilute, the distinction between the greater and lesser barons was forgot, and that opinion prevailed which my lord Coke had adopted, and which is now the law, that a man having once sat in parliament in pursuance of the king's writ, acquires thereby an estate tail to him and the heirs of his body.

There was yet another kind of persons, not peers, that might be summoned by writ: these were the eldest sons of peers, to whom the father's barony must descend; and in such case, if the heir was called by the name of a barony that was in his father, he was a baron to all intents and purposes. But it seems very plain that this was not a new creation of a barony, for in that case the son so called should have been the lowest peer, whereas the practice is contrary; and we find no instance of a baron's son sitting on such a summons, unless the father had another barony by which he might sit: if the father indeed had a higher title, that has been reckoned sufficient to support his fact, though his only barony was transferred to the son. Then being no new creation, but a temporary transfer only of an old peerage, it should seem that this title, when once merged in the greater by the father's death, should go according to the old limitation; but of late we find them considered as new creations. On the death of the earl of Derby, Sir Edward Stanley, his eldest cousin, succeeded, and sat in parliament as baron Strange by Henry the Seventh's creation; but an eldest son of another earl of Derby, having been called by writ while his father was living, the duke of Athol, as his heir by the female line, sat by the same title of baron Strange of King Charles the First's creation.

The descent of these two kinds of baronies is directed by the rules of the descent of other inheritances at common law; and, consequently, females are capable of succession, but with two exceptions: first, that half blood is no impediment, and, consequently, the half brother excludes the heir; secondly, that the honour is not divisible; and, therefore, if there be two or more heirs, if heirs, the title is in abeyance, that is, is suspended until the king makes choice of one of them and his heirs; though by conflict of law the title seems to be verging fast to a conflict between the eldest.

The third method of creating peers is by letters patent, which is the most usual, and was esteemed the most advantageous way; because the peerage is thereby created, though the new nobleman has never taken his seat, which is not the case of a barony by writ. As to the manner of these creations, there has been a notable difference intervened since the accession of Henry the Seventh from what was the practice before Richard the Second. In his eleventh year began this method of creating by patent, in favour of John de Beauchamp, who, though summoned, never sat there, but was attainted by the next parliament, and afterwards executed. But the attainder out of the cafe, his patent in law could never have been deemed valid, because Michael de la Pole was the lord chancellor who affixed the seal to it, which had been before taken from him by act of parliament, and he declared incapable of ever having it again. This was a single and ineffectual attempt of that weak prince to create a new peer without the assent of parliament, which was the usual way, above thirty having been made so in that very reign.

His successors were too wise to follow his example; for every barony newly created, till the union of the roes, which were about fourteen, was every one of them, as appears on the face of the patents, by authority of parliament; if we except two or three: and even these, on a close examination, will appear not to be new baronies, but grants of old feudal baronies by tenure, which undoubtedly were all in the sole disposition of the king.

But Henry the Seventh having trodden down all opposition, was fortunate enough to carry the point Richard had vainly attempted; and acquired for his successors that prerogative which they have since enjoyed of creating peers at pleasure. The descent of these titles created by patent is directed by the words of the creation: if heirs are not mentioned, it is only an estate for life; if to a man and heirs of his body, females are not excluded: but the general way is to the heirs male of the body lawfully begotten of the grantee, perhaps with remainders over, and they descend as other estates entail. The case of the duchy of Somerset was singular: Edward Seymour having three sons by two venters, was created duke of Somerset, and his heir male of his second marriage, remainder to his heirs male by his first. This title continued near two hundred years in the younger branch, until upon its failure in Charles the sixth duke of Somerset, Sir Edward Seymour, the heir by the prior marriage, succeeded by virtue of the remainder. Barons by ancient tenure, were those who held by certain territories of the king, who still reserved the tenure in chief
to himself. We also read of barons by temporal tenure: who are such as hold honours, castles, manors, as heads of their barony, that is, by grand serjeancy, by which tenure they were anciently summoned to parliament. But at present a baron by tenure is no lord of parliament, till he be called thereto by writ.

The barons by tenure, after the Conquest, were divided into majorés and minorés, and were summoned accordingly to parliament; the majorés, or greater barons, by immediate writ from the king; the minorés, or lesser barons, by general writ from the high sheriff, at the king's command.

The ancients distinguished the greater barons from the lesser, by attributing high and even sovereign jurisdiction to the former, and only inferior jurisdiction over smaller matters to the latter. By the late juridiction act (20 Geo. I.) the civil jurisdiction of a baron in Scotland is reduced to the power of recovering from his vassals and tenants the rents of his lands, and of condemning them in ill-services; and also of judging in causes where the debt and damages do not exceed 40s. sterling. His criminal jurisdiction is, by the same statute, limited to assaults, batteries, and other smaller offences, which may be punished by a fine not exceeding 20s. sterling, or by setting the offender in the stocks in the day time not above three hours; the fine to be levied by poinding, or by one months imprisonment. The jurisdiction formerly competent to proprietors of mines and coal or faltworks over their workmen, is reserved; and also that which was competent to proprietors who had the right of fairs or markets, for correcting the disorders that might happen during their continuance; provided that they exercised no jurisdiction inferring the loss of life or demembra tion.

Barons of the Exchequer are four judges, one of whom is called the chief baron, and the other three pujnice barons, to whom the administration of justice is committed in causes between the king and his subjects touching matters belonging to the exchequer, and the king's revenue. They are called barons, because barons of the realm were used to be employed in that office.

The lord chief baron is created by letters patent to hold this dignity quamdiu se bene geceftit, wherein he hath a fixed elate; for the law intends this an elate for life. He alone without the other barons sits at Guildhall the afternoon in term time upon nisi prius in London, takes suits, accompts, recognizances, presentations of offices, and many other things of importance. In the absence of the lord chief baron, the other three barons supply his place according to their seniority.

Their office is also to look to the accounts of the king, to which end they have auditors under them; as well as to decide causes relating to the revenue, brought by any means into the exchequer; so that of late they have been constantly persons learned in the law; whereas formerly they were majorés & dexteriores in regno five de clero eftnt, five de curia. See Court of Exchequer.

Barons of the Cinque Ports, are members of the house of commons, elected by the five ports, two for each port. See Cinque Ports.

Those who have been mayors of Corfe-castle in Dorsetshire, are also denominated barons; as were formerly likewise the chief citizens of London.

Baron, in Law, is also used for the husband in relation to the wife; which two, in law, are called baron and femme, and are considered as one person, so that in trials of any sort they are not allowed to be evidence for or against each other. See Husband and Wife.

Baron and Femme, in Heraldry, are terms used to express the arms of husband and wife; as thus, he beareth baron and femme. The modern expression is, he beareth impaled.

Baron, Court. See Court.

Baron, prender de. See Prender.

Baron, Robert, in Biography, a dramatic author, who lived during the reign of Charles I. and the protectorate of Oliver Cromwell. From Cambridge, where he received part of his education, he removed to Grays Inn, of the honourable society of which he became a member. At the university he wrote a novel called the "Cyprian Academy," containing two dramatic pieces, entitled "Dorcas Dowa," a tragedy, and "Gripos and Hegio," a pastoral. His tragedy of "Mirza," which is a more regular play, was probably written at a ripen age.

Baron, Richard, a celebrated French actor, was the son of a shop-keeper of Floudon, who himself went upon the stage, and born at Paris in 1672. He first joined the company of Raffin, and afterwards that of Molière, in which connexion he was universally admired and applauded. Baron was equally successful both in tragedy and comedy; although it is said he acquired his principal reputation in the former department. Racine, on occasion of introducing his Andromache on the stage, gave instructions to the other actors with respect to the performance of their several parts; but addressing Baron, who was to act Pyrrhus, he said to him, "To you, sir, I have no instructions to give; your own heart will tell you more than my lessons can inform you," Preachers are said to have attended in a grated box to fludy his action; and thence (says Voltaire) went to declaim against the theatre. Such was his vanity, that in allusion to the title that was bestowed upon him of the "Rolans" of his age, he said, that "every century produced a Cæsar, but that it required 2000 years to produce a Baron." He was highly careless by persons of distinction, although he sometimes was mortified by their reflections. At length, disgusted by this circumstance, or influenced by some other motive, he withdrew from the stage in 1691, and enjoyed a penion from the king. After an interval of 29 years he resumed his profession, and at the age of 68 was as much applauded as ever. In September 1729, his infirmities reduced him to the necessity of retiring, and he survived only two months. Baron was a writer as well as an actor, and composed several comic pieces for the theatre; which are said to be lively and amusing, and to exhibit much knowledge of the stage and of the world. He also wrote some poems. A collection of his works was published in Paris, in two vols. 12mo. in 1736; and in three vols. in 1760. But some of the pieces contained in this collection are supposed not to be his. Voltaire's Age of Lewis XIV. Nouv. Dict. Hifor.

Baron, Bonaventure, whose true name was Fitzgerald, was a native of Connell, in the county of Tipperary, in Ireland, and educated under the care of his uncle Luke Wadding, a Franciscan friar at Rome, who induced him to assume the habit of this order. He resided at Rome, where he was for a considerable time prefect of divinity in the college of St. Ignace, founded by his uncle in 1625, about 60 years, and died there, after having lost his sight, and at an advanced age, in the year 1696. He was distinguished by the purity of his Latin style, and wrote many books both in prose and verse in that language. His chief work was his "Theologia," in 6 vols. printed at Paris in 1676. Bing. Brit.

BARONET of ENGLAND, an hereditary dignity by patent, next to that of a baron instituted by king James the First on the 22d of May 1611. The first baronet that was created was Sir Nicholas Bacon of Redgrave in Suffolk, who
whole successor is therefore styled Privus Baronorum Ang.

lie. At the first institution of this order the king engaged that the number should not exceed two hundred, and that each should pay into the exchequer as much as would pay thirty foot soldiers at eight-pence per diem to serve in the province of Ulster in Ireland; and for their distinction, as an honourable augmentation, they bear in their coat of arms either in a canton, or in an escutcheon of pretence, the arms of the ancient kings of Ulster, being argent a bend, gules, couped at the dexter, extended in pale gules. Baronets and their eldest sons have this peculiar privilege, that they may be knighted if they please, upon knowledge thereof given to the lord chamberlain of the household, or vice-chamberlain for the time being, or in their absence, to any other officer attending his majesty's person; and in all communications,把持, and other deeds, the style of baronet is to be placed at the end of their surnames, as a necessary and legal addition of dignity, as the addition of Sir is to be placed before their Christian names, and to their wives the title of Lady or Dame. Baronets have precedence before all knights, except those of the garter, and knights bannerets. No patent for creating a baronet can now pass the great seal until the following certificate is obtained.

"To all and singular to whom these presents shall come, the king's heralds and purveyors of the College of Arms, London, do hereby certify that the family, arms, and pedigree of have been duly registered in this college pursuant to the tenor of his majesty's warrant under his royal signet and sign manual, bearing date the day of 1783, for correcting and preventing abuses in the order of baronets. In witness, &c."

Baronets of Ireland, an hereditary dignity instituted 30 Sept. 1691, the same as thence in England, and bearing likewise the arms of Ulster as an augmentation.

Baronets of Nova Scotia. This order is also hereditary, and was instituted in Scotland by king Charles I. on 28th May 1625, for advancing the plantation of Nova Scotia in America, and for settling a colony there, to which the aid of these baronets was designed. As an augmentation to their arms, they bear either in a canton or in an escutcheon the arms of Nova Scotia, being argent a crescent of St. Andrew arme charged with an escutcheon of the royal arms of Scotland; supported on the dexter by the royal standard, and on the sinister, by a staff or, withitial part; and for the crest, a branch of laurel, and a thistle, issuing from two hands combined, the one being armed and the other naked, with this motto: Nulli hoc et altera vincit: and for their greater honour and dignity they were, by royal sign manual, bearing date 17th Nov. in 1629, allowed to bear and carry about their necks in all time coming an orange-tawny silk ribbon, whereon shall hang pendant in an escutcheon argent a falter azure thereon an escutcheon of the arms of Scotland with an imperial crown above the escutcheon, and inscribed with this motto: Pax mentis honos gloria.

BARONIÆ CAPUT. See CAPUT.

BARONIUS, Caesar, in Biography, a learned cardinal, was born at Sora, in the kingdom of Naples, in 1535, and educated first at Veroli, and then at Naples. Having finished his studies at Rome, he entered in 1560 into the congregation of the oratory founded by St. Philip de Neri, and having received the order of priesthood, he was elected superior-general of the congregation, upon the death of its founder in 1583. Pope Clement VIII. chose him for his confessor, made him apostolical protonotary, and in 1596 raised him to the dignity of cardinal. He was afterwards made librarian of the Vatican. On the death of Clement, he had many votes in the conclave for the pontificate; but the Spanish party prevented his election, because he had adhered in his annals, that the crown of Spain founded its title to Sicily on false evidence. His abundant application to the length of 617, and his name at 68 years. His character was distinguished for piety and probity, and mildness of disposition, as well as for extensive erudition. His chief work was his "Ecclesiastical Annuas," which he began at the age of thirty, and prosecuted through the greater part of his life. Of these he lived to publish 12 vols. in folio, the first of which was printed in 1588, and the last in 1607; and he brought down the history of the church to 1598. This voluminous and elaborate work was undertaken with a view of counteracting the influence of the protestant compilation by the cenotaphs of Magdaburg, which was intended to expunge the abuses and inconstancies of the Romish church; and the author, adorning rigidly to his main object, and approving himself a bigoted partizan of the see of Rome, has on many occasions furnished truth to the prejudices and interests of a party. He has been charged even with intentional misrepresentations; and he has been betrayed by his imperfect acquaintance with the Greek language into many errors, and by his crudity into the recital of many fables, which have been rejected by many judicious writers of his own party. The work, however, is a monument of affinity and labour. It is methodically conducted, and upon the whole it is an useful, though sometimes a fallacious guide in the chronological history of the events that happened under the Roman emperors. The style, though not pure and elegant, is generally perspicuous. Amongst the critics and enquirers of this work, we may reckon both protestants and catholics. The learned Isaac Casaubon undertook a refutation of the Annals of Baronius, in a work intitled "Excercitaciones, &c." and though he closed it with the 34th year of the Christian era, he pointed out a great number of palpable errors into which the Roman annalist had fallen during that short interval. Even the Roman catholic literati acknowledge the inaccuracies and faults of Baronius; and hence Pag, Norris, and Tielman, &c. have been employed to correct them. Accordingly, a new edition of these "Annuas" was published at Lucca, in 1733, with the corrections of those refutations. The original work was first printed at Rome, and soon after at Antwerp by Plantin; and editions have also been published at Cologne and Venice. Abridgments of it have also been published by several persons. About two years before the appearance of the "Annuas," Baronius published a kind of preface, intitled "Martyrologium Romanae rellitatum," &c. or "Notes on the Roman Martyrology," folio, 1586: and afterwards often printed with corrections. Mulheim's Ecc. Hist. vol. iv. p. 265. Cave's Hist. Lit. tom. i. Prolegomena. p. 6. &c.

BARONIUS, Theodore, of Cremona, in Italy, published in 1609, in 4to, "De operationibus medicinali Factionis et curaciorum, in quibus medicini, et aliarum artium, exercitationes, ut medicinae, Galeni praetexta movantur, peractantur." He was a zealous defender of the doctrines of Galen, with whom, he says to have declared, it is more credible to err, than to reason right on any other system: but he has in some points left his guide. He recommends the use of cantharides internally in affections of the kidneys and bladder, a practice it is probable Greenesveldt learned from him: he also injected medicated liquors into the bladder, with the view of facilitating the egress of calculi, or of dissolving them. Hall. Bib. Med.

BARONIUS, Vincentius, a celebrated Italian physician, published in 1630, 4to. "De peripueum, anno 1633, et alia
BAR

BARONHLA, in Geography. See LASSA.

BARONY, BARONIA, or BARONAGIUM, the lordship or fee of a baron, either temporal or spiritual; in which sense barony amounts to the name with what is otherwise called honour.

A barony may be considered as a lordship held by some service in chief of the king, concurring with what is otherwise called grand serjeanty, and being their first creation, moved from the king himself, the chief lord of the whole realm, and could be holden immediately of no other lord. For example, the king enfeoffed a man of a great feigneurie in land, to hold to the person enfeoffed and his heirs, of the king and his heirs, by baronial service, to wit, by the service of twenty, forty, sixty knights, or of such other number of knights, either more or fewer, as the king by his enfeoffment limited or appointed. In the ages next after the Conquest, when a great lord was enfeoffed by the king of a large feigneurie, such feigneurie was called a barony, but more commonly an honour; as the honour of Gloucester, the honour of Wallingford, the honour of Lancaster, the honour of Richmond, and the like. There were in England certain honours, which were often called by Norman or other foreign names; that is to say sometimes by the English, and sometimes by the foreign name. This happened when the same person was lord of an honour in Normandy, or some other foreign country, and also of an honour in England. For example, William de Forz, de Force, or de Forthibus, was lord of the honour of Albemarle in Normandy, he was also lord of two honours in England, to wit, the honour of Holderness, and the honour of Skipton in Craven. These honours in England were sometimes called by the Norman name, the honour of Albemarle, or the honour of the earl of Albemarle. In like manner, the earl of Brittany was lord of the honour of Brittany in France, and also of the honour of Richmond in England; the honour of Richmond was sometimes called by the foreign name, the honour of Brittany, or the honour of the earl of Brittany. This serveth to explain the terms, honour of Albemarle in England, honor Albemaris, or comites Almariae in Anglia; honor Brittany, or comites Britanniae in Anglia, the honour of Brittany, or the earl of Brittany in England. Not that Albemarle or Brittany were in England, but that the same person respectively was lord of each of the said honours abroad, and of each of the said honours in England. The baronies belonging to bishoprics are by some called regalia, as being held solely on the king's liberality. These do not confine in one barony alone, but in many; for totient baronie, quot majora praedita. See Bishop.

A barony, according to Bacon, is a right indivisible: wherefore, if an inheritance be to be divided among the copar-
BAR

Invermemshire, in Scotland, has remained for many ages in the possession of the Macnabics of Barraw or Barra. It is well forested with black cattle, and fruitful in barley and oats. The manufacture of kelp is carried on with considerable profit in this island. Cod and ling are caught on the coast in great quantities; and the fishermen also take some dry fish, the oil of which they burn in their lamps, and they fell that is not consumed by themselves at 7d. or 8d. the Scots pint. Shell-fish, and particularly cockles, are abundant; the cockles are found in the great sand at the north end of the island, and afford a plentiful supply of sustenance to the inhabitants. The fishery, however, has been much neglected. This island is somewhat hilly; in extent it is nearly 8 miles long and 4 broad; it is populous notwithstanding the late emigrations to America, and it is said to contain about 16,44 inhabitants. The natives are in general Roman Catholics. It is situated nearly south from South Wilt, and adjoins communicates with Benbecula at low water, and on this account they are both comprehended sometimes under the name of Long Isla. Its coast on the west side is low and flat, but on the east side steep and irregular. N. lat. 57° 25'. W. long. 57° 30'.

BAR. A lord of Ireland, in the county of Donegal, through which the river Guaibara flows: 20 miles north of Donegal.

BARRABA. See Baraba.

BARRABOA, a town of Africa, in the country of Magdaxa.

BARRACO, a lord of Ireland, in the county of Monaghan, on the western side of which is situated the town of Cattie Blaney.

BARRACKS. See barracks.

BARRACOL, in Ichthyology, a name given by Arcted, from the Venetians, to express the species of ray-fish, called by Bellonius and Gehr miraletus, and by others risa ovulata bosii.

The specific name of Arcted carries in it a much better notion of the kind: he calls it the ray, with a smooth back and belly, and with the eyes surrounded with a series of spines, and three other rows of them on the tail.

BARRA COUVA, in Geography, a town of Africa, in the country of Negro, situated on the river Gabba.

BARRACOO, or as the sailors call it, Berra, or Berke, lies on the west coast of Africa, 6 or 7 leagues W. S. W. from Agra, and is known at sea by two very high mountains behind it, one of which is double at the top with a saddle, and they are covered with trees. Some rocks lie off in the sea just before it, and form a kind of haven.

BARRACOPE, lies on the west coast of Africa: seven leagues E. S. E. from St. Mary's, and at the same distance from the river Junk in the same direction on the other hand. This coast abounds with negro towns, and also with trees and water.

BARRAD, a town of Arabia, 40 miles south-east of Saude.

BARRADY. See Barady.

BARRAGAN, or Baracan, in Commerce, a kind of flax belonging to the class of commodics, only of a grain much coarser than the red, manufactured in divers parts of France and Flanders, chiefly at Abbeville, Amiens, Rouen, and Lille, and now in England.

The word is barbarous Latin, formed as some suppose, from barba, g. d. barraun fornun referens. Du-Cange. The chief use of Barraganis, called also by the French Bourcain, is for outwears, or upper garments against the rain, being, when new, of wool cloth and grain, that the water will not soak through, but only run upon them.

Vol. III.

For the wool, its thread is single, twisted, and fine spun, that of the warp is double or triple; i. e. composed of two or three threads well twisted together. The stuff matter it is made of, is wool; though there are some made of cotton, where the warp is hemp, and the wool wool. Some Barraganis, again, are made of wool, dyed before it comes to the loom; others are woven white, and dyed afterwards, red, black, blue, brown, &c. They are not failed, but only boiled two or three times in warm water, when they come from the loom, then calendered to make them strong and even; and lally, made into rolls called pieces of Barragan.

BAREL, Peter, in Geography, a French sugar, was born at Grenoble, and removed to Paris, at an early period of his life, took up the office of a school master. He died there July 21, 1772. His chief literary work is a "Dictionnaire historique, litraire, et critique des Hommes célèbres," 6 vols. 8vo. 1759. It was accompanied the Morality of Janzimii, compiled by a convulsionnaire. Although this work betrays too much of the spirit of party, the articles of learned authors, poets, orators, and literary men, are generally compiled with judgment and taste. Barel has also published an abstract of the letters of Madame de Sevigné in 12mo. under the title of "Sevigniana," and a valuable abridgment of the "Dictionnaire des Antiques Romans," by Philostratus, in 2 vols. 8vo. He was a man of judgment, and of lively conversation; and the force of his writings is vigorous and nimble, though sometimes negligent and incorrect. Bog. Dict.

BARRA-MAHAL, or Bara Mahal, denoting the "twelve places," in Geography, a valley called also Vaniam-baddy, in the peninsula of India, containing twelve fortresses of some note: viz. Kiflajgheri, Jezdjidj, Candei, Con-gooda, Vaniam-baddy, Mahrauzgar, Coehingur, Cou-tugur, Basingur, Tripatore, Tadcul, and Giggangury.

BARRAN, a town of France, in the department of the Gers, and chief place of a canton in the district of Auch, containing about 700 inhabitants; 2 leagues W. S. W. of Auch.

BARRANCA, a town of South America, in Peru, with a harbour in the Pacific ocean. The jurisdiction of Guara begins at this town. The number of houses does not exceed 60 or 70, and yet the town is populous, many of its inhabitants being Spaniards. Near the town is a river of the same name, which divides into three branches. The port is to the west of a small low point. S. lat. 10° 30'. W. long. 43° 4'.

BARRADA, in Ancient Geography, a town of Asia, in Pamphylia. Pitrecus.

BARRATI, barrat, an appellation given to the Cartamini after they were obliged to lay aside the white cap, and wear cowls wrapped black and white.

Barratry is used for bribery or corruption in a judge giving a false sentence for money.

BARRATRY, in Commerce. See Baratry.

This term comprehends any species of fraud, knavery, deceit, or cheating, committed by the master or owners of a ship, by which the owners suffer an injury, as by running away with the ship, wilfully carrying her out of the course prescribed by the owners, faking or deterring her, embrazing the cargo, smuggling, or any other offence, whereby the ship or cargo may be subject to arrest, detention, loss, or forfeiture. Hence, in cases of insurrection, if the branch affixed in the declaration on a policy was the loss of the ship "by the fraud and negligence of the master," this was determined to be a sufficient averment of a loss by barratry. At Amsterd'am, Hamburg, Middlesburgh, and some other maritime towns, insurers are, by positive law, made
made responsible for the barratry of the master and mariners. With us the law permits the owner of the ship to be injured against the misconduct of the captain and crew, though they are his own agents, and the perils of his own choice. If the captain be the injured, no agreement on the part of the insurers can make them liable for barratry committed by himself; but they may be liable, in such case, for the barratry of the sailors, in which he has no part. With us no fault of the master or mariners amounts to barratry, unless it proceed from an intention to defraud the owners of the ship. Therefore if the master from ignorance, unskillfulness, or from any motive which is not fraudulent, depart from the proper course of the voyage, this will be a deviation which will avoid the policy, but it will not amount to barratry. In France if by the policy the injured be protected against the barratry of the master, the underwriters are answerable for the misconduct of the sailors also; because the term master (patron) comprehends all the persons on board who are in the ship's pay. Our policies are more explicit, and distinctly specify barratry of the master and mariners. Hence it has been concluded, that with us, as in France, the mariners may commit barratry, without the concurrence of the master, or against his will. Nevertheless it has been held by Lord C. J. Lee, at Nîéh Prins, that a deviation to which the master was compelled by a very daring act of violence and disobedience on the part of the seamen, did not amount to barratry, because the ship was not actually run away with in order to defraud the owners. The insurers, therefore, were held to be answerable, and the plaintiff had a verdict. This learned judge seems to have thought, that nothing short of running away with the ship, with the intent to defraud the owner, amounted to barratry: and yet in another case, the conduct of the master was held to be barratry, though certainly much more venial than that of the sailors in the former case. Hence it has been inferred, that though the captain conceive that what he does is for the benefit of the owners, yet if it be contrary to his duty to them, it is barratry. An owner himself cannot commit barratry; neither can it be committed against the owner, with his consent. If the master of the ship be also the owner, he cannot commit barratry, because he cannot commit a fraud against himself. Although it be a maxim in law, that fraud shall never be presumed, but must be strictly proved; and it is a rule in questions of insurance, that he who charges barratry must substantiate it by conclusive evidence; yet a case has occurred, in which it was determined, that proof of the master's having carried the ship out of the regular course of the voyage for fraudulent purposes of his own is prima facie sufficient to entitle the plaintiff to recover, without showing negatively that he was not the owner, or that any other person was the owner, or that this was not done with the owner's consent. Though the words "in a lawful trade," he inferred in the policy, fill the insurer is liable, if the captain commit barratry by smuggling on his own account. It appears, that it a loss do not happen within the time prescribed by the policy for the duration of the risk, the insurer will not be liable for it, though it be the undoubted conference of the act of barratry.

The offence of barratry, in itself so heinous, and so injurious to commerce, is punishable as a public offence, according to the guilt of the offender, by every commercial statute in Europe. In France, any fraud practiced by the master or mariners, with or without the privity of the owners, and frauds committed by the owners themselves, are accounted barratry, and very severely punished. The captain of a ship was sentenced to the galleys for life, for signing false bills of lading in order to change the voyage and carry away the goods; and the owner, who was convicted of being an accomplice in this crime, and of robbery in causing the ship to be carried to a wrong port, and converting the goods on board to his own use, was sentenced to the galleys for five years. With us the Stat. 1 Ann. 8. 2. c. 9. § 4 & 6, makes it felony to defraud any ship to the prejudice of the owners of the ship or goods on board, and takes away the benefit of clergy from such offences, committed on the high seas. By Stat. 4 Geo. I. c. 12. § 3, if any owner, captain, master, mariner, or other officer of any ship, shall wilfully cast away, burn, or otherwise destroy the ship of which he is owner, or to which he belongs, or in any manner defeat or prejudice the same to be done to the prejudice of the peron or perons that shall undertake any policy of insurance thereon, or of any merchant that shall load goods thereon, he shall suffer death; and the Stat. 11 Geo. I. c. 29, takes away clergy from such offenders in all cases. Marshal's Treatise on the Law of Insurance, vol. ii. chap. 13. See Pirate.

Barratry is also used in the law of England for the offence of striking up frequent suits and quarrels among his majesty's subjects. The term, however, is of foreign origin; and in Italy and other countries seems ordinarily to have been applied to the traffic of ecclesiastical benefices; but was afterwards used in a more general sense, as applicable to all corrupt buying and selling of places. In Scotland it signified the corrupt purchasing of benefices or offices of collection, from the see of Rome, by persons who left the realm for that purpose; a practice, which had been frequent, and was in various respects injurious to the realm, as a means of carrying money out of it, without any return of value, as prejudicial to the right of patronage in the king and others, and to the free elections of the monks in the monast. res, both which the pope by prevention pretended to exclude, and as contributing to raise the rate of taxation upon benefices, by the false accounts which these suitors for the office of collector carried to the pope. See Barre.

Barre, Lewis Francis Joseph Dr. La., in Biography, was born at Tourain in 1668, and educated at Paris; where he applied to the study of the ancient languages and to the collation of MSS., with such facility, that he was recommended to André Bandéri, the learned Benedictine, as a proper efficient in his antiquarian researches. In consequence of their joint labours, they published the "Imprimis Orientalis" and the collection of the Roman emperors from Diocletian. For these services Barre had a pension from the grand duke of Tuscany. He also gave a new edition of the "Spicilegium" of Luke d'Achery in 3 vols. 4to, printed at Paris in 1723. He had also a considerable share in the new edition of "Moret's Dictionary" of 1725. In 1727, he was elected a member of the Academy of Inscriptions, the memoirs of which he enriched by several valuable papers, historical, chronological, geographical, and miscellaneous. He also published, in 1729, in one vol. 4to, "Memoirs for the History of France and Burgundy," known under the title of the "Journal of Charles VI." Besides other publications of a less important nature, he finished more than 100 select articles of a new and ample dictionary of Greek and Roman antiquities; but he was prevented by death, in 1736, from completing his undertaking. Moret.

Barre, Joseph, a learned historian, was born in 1652; and entering into the church, he became first a regular canont of St. Genevieve, and afterwards chancellor of the university of Paris. He was distinguished for piety and erudition, and for his industry as a writer. His principal works include "Mémoires pour l'historie de France et de Burgundie," known under the title of "Journal de Charles VI." Besides other publications of a less important nature, he finished more than 100 select articles of a new and ample dictionary of Greek and Roman antiquities; but he was prevented by death, in 1736, from completing his undertaking. Moret.
BARRELS. In Geography, a town of France, in the department of the Aisne, and chief place of a canton in the district of Soissons. It has 5430 inhabitants; the territory includes 150 square kilometres and nine communes. The town has good pastures, fattens a multitude of cattle, and produces more butter and cheese for the market than any other of the same extent in the state.

BARREL, in a town of France, in the department of the Aisne, and chief place of a canton in the district of Soissons, 3 leagues S. of Soissons, and 63 W. N.W. of Amiens. The place contains 490 and the canton 5430 inhabitants; the territory includes 150 square kilometres and nine communes.

BARRELS, also a township of Huntingdon county in Pennsylvania.

BARRE, a clear or district of Hindostan, in the country of Gunjrat.

BARREL BAY. See BAX.

BARREGES, a town in the department of the Aisne, and chief place of a canton in the district of Soissons, 3 leagues S. of Soissons, and 63 W. N.W. of Amiens. It has 5430 inhabitants; the territory includes 150 square kilometres and nine communes. The town has good pastures, fattens a multitude of cattle, and produces more butter and cheese for the market than any other of the same extent in the state.

BARREL, an oblong vessel, of a spherical, or rather a cylindrical figure, used for the holding divers sorts of goods both liquid and dry. Barrels are of divers sizes in Artillery, as for powder, small shot, flints, sulphur, salt, pitch, quick-match, and many other things.

Barrels filled with earth serve to make a parapet to cover the men, like g-bions and canvas bags.

Barrel barrels are cells of divers capacities, filled with bombs, grenades, fire-ports mixed with great quantities of powder packed in petrol, turpentine, pitch, &c. The barrel was used by the besiegers to defend breaches. There are sometimes called thunders for barrels, being to be rolled down on the enemy on entering the breach.

Barrel is also used for a certain quantity, or weight of several merchandizes; which is various as the commodities vary.

The English barrel, wise measure, contains the eighth part of a tun, the fourth part of a pipe, and the moiety of a hoghead, that is, thirty-one gallons and a half; of beer it contains thirty-six gallons, and of ale thirty-two gallons.

The barrel of beer, vinegar, or liquor preparing for vinegar, is to contain 34 gallons, according to the standard of the ale quart, 10 and 11 W. III. cap. 21.

The barrel of herring is to contain 32 gallons, wine measure; being about 28 gallons, old standard, usually amounting to about 100000 full herring, 13 Esth. cap. 11.

The barrel of salmon is to contain 42 gallons, 5 C. cap. 18. And the barrel of ells the same, 22 Ed. IV. cap. 22.

The barrel of soap is to contain 526 gallons, 10 A. cap. 19.

A barrel of Ee7x butter weighs 166 pounds, and of Suffolk butter 256 pounds.

In some parts of Ireland, particularly in the city of Cork, coals and salt are measured by the barrel. The barrel used to contain 7 buthels Winchelsea, but that lately introduced for coal is, according to law, 4 buthels; i.e. 40 English, or 50 Irish gallons. Salt is still measured in the barrel of 7

bulk, but fible measure; whereas the coal was sold by hoop measure, which put it into the power of the measurer to cheat either the seller or buyer at pleasure. The abufe was found so great that this kind of measurement has been abolished.

The barrel or barile of Florence is a liquid measure containing 20 st. quarts, flalles, or one third of a bar or hale.

The barrel, bauple, of Paris, contains 210 points, or 26 septairs and a half; four bariles make three muids, or one ton.

Barrel, in Anatomy, denotes a pretty large cavity situated behind the drum of the ear, lined with a membrane in which there are several veins and arteries. It is said to be full of a purulent matter in children; and in its cavity there are four small bones; viz. the malleus, the incus, the stapes, and the osseous.

Barrel of a Clock, in Mechanics, is a cylindrical part, about which the thing is wound. And the barrel of a watch is the cylinder which contains the spring, and about which the chain coils.

Barrel of a Gun, Pilothole, &c., is the cylindrical tube through which the ball is discharged.

Barrel of a Jack, is the cylindrical part wherein the line is wound.

Barrel of a Pump, is the wooden tube which makes the body of the engine, and wherein the piston moves.

BARRELET, in Heraldry. See BARRELT.

BARRELLIER, JAMES, in Biography, a Dominican monk, was born at Paris, in 1606, of a noble family. Having received a liberal education, and being well skilled in Latin, Greek, and several modern languages, he applied himself to the study of medicine; but entering among the Dominicans, in 1635, he now confined himself to acquiring a knowledge of plants. With this view, he embraced an opportunity of accompanying the head or general of the Jacobins, as an assistant, with whom he travelled over a great part of France and Spain, collecting everywhere whatever rare plants could be found, of which he procured drawings to be made. At the end of 23 years, a great part of which was spent in Italy, he returned to Paris. He now applied himself in arranging the plants he had collected, proposing to publish them in various volumes, and were deposited, after his death, in the library of the Jacobins at Paris, where they remained until the year 1714, when Antonine Joffieu undertook to publish them, under the title of "Plantae per Galliam, Hispaniam, et Italiam observavt, et iconibus stucco exhibitae, a R. P. Jacobo Barrellier, opus posthumum;" Paris, 2 vol. fol. The engravings are on a small scale, frequently borrowed from other works, Haller says, and many of them repetitions of the same plants. Many of them, however, he adds, are new, and of scarce and valuable plants, which entitles these volumes to a place in all botanical libraries. Haller, Bib. Botan. Flev. Dict. Hirt.

BARRELING, the art of putting up certain commodities in casks or barrels.

Gun-powder for the land service is often barreled double, the barrel it is put in being enclosed in another barrel, partly to prevent the powder catching moisture in the subterraneous places it is kept in, and partly to enable it to be better handled and to enable the powder to be moved and to be conveyed to another place.

Barreling of Herings, imports the cutting off their heads as they are thrown into the barrels, and afterwards pulling

4 U 2
ing out the guts, salting them, and putting them up in
barrels. There are two sorts of barrelled herrings; one
wherein they are laid orderly, layer over layer, called by
some packed herrings; the other wherein they are thrown
at random, called herring in wrack.

The difference arises thus: as fast as the fishermen catch
these herrings, they throw them on the deck of the vesel;
where have noised and salted them, they throw them at
random into the barrel, to be carried home; this is the her-
ring in wrack.

When arrived above, they take the fish out of these bar-
rels, cast them into a tub, and salting them anew, range them
landlocked in their barrels again, laying salt over them, to
preferve them; these are the packed herrings. And it is in
the same that they are usually fold.

Barrel's Sound, in Geography, lies on the N.W.
coast of America, and is called by the natives Conger-bay.
It's bountied about 6 leagues from the southern extremity
of Washington or Charlotte islands; is a N.W. direction, about
N. lat. 52°, W. long. 135°. It has two islets, one on the
exit, the other on the west side of the island: the latter is
the smallest, the other is dangerous. The shores are of a
craggy black rock; and the banks are lined with trees of
various kinds; as pines, fir, hick, birch, elder, &c. This
sound was first visited by Capt. Gray in the Dartmouth in
1789, and derived its name from Joseph Barrel Eq. of
Charlestown.

Barrels, the name given to rocks near the south coast
of the county of Wexford, in the Irish sea, 5 miles S.W. of
Carnfore point. Also, to rocks near the S.W. coast of
Ireland, in Courtrinchay bay.

Barren, a town of France, in the department of
the Lower Alps, and chief place of a canton in the district
of Digne, 10 miles S.S.E. of Digne. The place contains
843, and the canton 3348 inhabitants; the territory in-
cludes 2175 square kilometres, and 8 communes.

Barren, a term of Saxon origin, and means, applied
to animals or vegetables, unfruitful, sterile, incapable of
producing or propagating its like. Land is called barren, on
which no plants, fit for the fullest or nourishment of
man or animals, will grow. Metaphorically applied to the
human mind, it means dull, stupid, uncomptive.

In man and animals barrenness is usually occasioned by
some defect in the organs of generation. Both sexes are
liable to this defect; but it is thought to be more inci-
dent to the female than the male. It is remarkable, that
hybrid animals, as the mule, are incapable of propagating
their like. See HYBRIDS.

Barrenness may also be occasioned by general debility, or
ill health; and yet women in nearly the last stage of con-
fumation, are not unfrequently found to conceive, to carry
the fruit to its full term, and at length produce it in a
found and healthy state; the progress of the consumption
being stopped during the time of utero-gestation. See
Gestation.

Defects, occasioning barrenness, or sterility, are either ex-
ternal or internal. The most usual external deficiency in
men, is, a penis too short, slender, or feeble. This state of
that organ is often attended by a degree of curvature, the
end being held down by a strong bridle. In these cases, the
orifice of the urethra, instead of being at the end, is in
the under part of the penis, within half an inch of its
extremity; whence there is not only considerable difficulty in
introducing it into the vagina of the female, but in the
venerable orgasm, the semen, instead of being thrown for-
wards towards the os uteri, is ejected backwards, and so
lost.

In the female, straitness of the vagina, or conchion of
its fides, preventing the intromission of the male organ, may
occasion barrenness. These defects may sometimes be
remedied by appropriate operations. (See VAGINA, DISEASES
of.) The same effect, a straitness of the vagina, may be
occasioned by fibrous affections of its fides (see above).

But a more common case is an expansion of the membrane
called the hymen, shutting up the entrance of the vagina,
and only having, at the anterior part, a small hole for the
passage of the urine. Midwives are therefore cautioned, on
the birth of female children, to examine whether the passage
into the vagina be open, and if they find it covered by a thin
membrane, to separate it with their nails, and to inspect the
part for a few subsequent days, that it may not coalesce again.
If this caution has been neglected, the membrane, which at
the birth of the child is so tender as to yield to the
flightieft force, becomes, in a few years, thick, firm, and
fleshy, and can only then be divided by a painful and trou-
blesome operation. See HYMEN, IMPERFORATED.

The vagina is also sometimes found divided into two
canals or passages, by a strong, fleshy, membranous pari-
tion, running its whole length, or nearly so, rendering the
introduction of the male organ difficult or impracticable.
These two passages sometimes communicate at the upper
end, and receive a single os uteri; at others, they continue
separate, terminating, or each of them leading to an os
uteri; the uterus having, in these cases, two cavities, or
there being two uteri. (See the articles VAGINA, and
UTERUS.) These, however, may be considered as causes
rendering impregnation difficult, but not impossible. More
certain and inevitable causes of barrenness in women are,
imperviousness, scherhus, or other diseases of the os uteri,
Fallopian tubes, or of the ovaries, which are generally in-
curable.

Dbility, occasioning barrenness in men particularly, is
most commonly caufed by the too early, or too frequent,
and indiscriminate use of venery, by masturbation, or self-pollu-
tion (see ONANISM), by repeated attacks of gonorrhoea
or syphilis, by gleet, and by frequent and long continued
courses of mercury. For the cure of these complaints, see
GONORRHOEA, LUES VENEREA, GLEETS; see also CON-
CEPTION, Causes impeding.

Barren Corn, in Agriculture, a term applied to a dilem-
per in corn, in the which the ears of such kinds as are affected,
as wheat and rye, which are the most subject to it, are long,
lean, and white; in rye, the stamens, or small threads in the
middle of the flower, are dry, transparent, and horned; the
female organs are small, white, and lew veleky than in
healthy ears; in others, the filamentis are divided, the apices
or knobs on the tops of the stamens void of dust, or torina,
and the stigma bafed unfolded. The stigma of all the blossoms
of an ear are sometimes dried and parched, and at other
times the apices are much twelled out. This dilemper of
corn has been ascribed to various causes; such as its too
hudden growth, the influence of frost or other plieas of
sunshine after heavy showers; and sometimes, though rarely,
to infects. C.ount Giammati impites it to the faltiness of
the foid; and he recommends particular attention to the
amendment of it by such means as are best suited to its
nature; and he also directs to change the feed every
year.

Barren Earth, a term given by some writers to particu-
lar fertile soils, and also to the under stratum of earth, or that
which lies immediately below the bed of mould, which is
most frequently turned up and cultivated for the nourish-
ment and support of plants. The idea of the under strata
of soils being improper for the growth and support of plants
seems to have originated in error, as it is now well known
that every kind of earth, whether placed near the surface
Bar

or at a considerable depth below it, is capable of affording the support of plants, when well broken down and rendered sufficiently mellow by ploughing, and the influence of the atmosphere.

Barren Lands, are such as either naturally, or for want of proper tillage and cultivation, do not on being sown produce good crops or such as are sufficient for repaying the expenses of the cultivator.

Barren Menu, in the Civil Law, denotes that which is not put out to interest.

Barren Soil, in Agriculture, are those which, from the nature of their constituent ingredients, are incapable of affording full crops. The materials which enter into the composition of such soils are, according to Mr. Kirby, flint, argill, and calx, in the following proportions.

Silex from 42 to 88
Argill 20 39
Calx 4 20

From which he concludes the Troy pound to contain, allowing 120 grains for water, of

Silex from 2368 to 4073
Argill 1181 1622
Calx 685 600

The specific gravity in such soils has not been fully ascertained, but the same writer supposes it to be either much above or greatly below that of other kinds, according as they are too close or too open and porous. That of barren sandy land was found by M. Fabroni to be 2.51. See Soil.

Barren Springs, in Rural Economy, such springs as are injurious to lands when suffered to flow or run over them. Waters that flow from coal mines, or through mineral parts, have frequently been observed to have this pernicious quality; and fish also as contain either alumina or ferruginous materials in a state of solution in them.

Barren Flowers or Flowers, called also abortive, in Botany, are such as produce no perfect seeds. The barren flowers are such as have stamens, but no pistils; and they are also called male flowers. Flowers which have only pistils, are sometimes barren, owing to the absence of other flowers, which bear the stamens. In the umbelliferous flowers, it is not uncommon to have several of the florets barren, though they are furnished both with stamens and pistils; perhaps owing to some imperfection in the pistils; but future observations must determine this matter.

Barren Creek, in Geography, rises in the N.W. corner of Delaware late in America, runs about 9 miles S.W. and discharges itself into Nanticoke river. A triangular tract of land in the N. part of Somerset county, Maryland, is inclosed between this creek on the S., Delaware Rtes E., and Nanticoke river on the W. and N.W.

Barren Island, a small isle in Chesapeake bay, N.E. from the mouth of Patuxent river, which is separated from Hooper's island by a narrow channel on the east.

Barren Island is also an island in the East Indian ocean, about 6 leagues in circumference. The whole island has a singular and volcanic appearance; and there is upon it a violent volcano, which emits immense volumes of smoke, and flowers of red hot stones, some of which weigh 3 or 4 tons, and are thrown some hundred yards beyond the foot of the cone. The base of the cone is the lowest part of the island, and very little higher than the level of the sea. It rises with a acclivity of 35° 17' to the height of 1800 feet nearly, which is also the elevation of the other parts of the island. Those parts of the island that are distant from the volcano, are thinly covered with withered shrubs and blasted trees. It is situated in N. lat. 12° 15', and 15 leagues to the call of the easternmost cluster of the Andaman islands, and may be seen at the distance of 12 leagues in clear weather. At a quarter of a mile from the shore, there is no ground with 150 fathoms of line. Asiatic Researches, vol. iv. p. 276, &c.

Barren Illes, lie on the N.W. coast of America, at the entrance of Cook's inlet. These illes, situated in N. lat. 58° 48', and E. long. 268° 30', and cape Elizabeth, situated in N. lat 59° 5', and E. long. 268° 53', according to Vancouver's chart, form a channel into Cook's inlet.

Barren River, a name given to each of the S. E. branches of Green river, in Kentucky; between which lies Blue Spring.

Barrenness. See Sterility

Barrenwort, in Botany. See Epimedium.

Barréone, in Geography, a river of Piedmont, which runs into the Vulfixus, near St. Martin, in the county of Tenda.

Barrere, Peter, in Biography, professor of medicine, physician to the military hospital at Perpignan, his native country, retired three years at Cayenne, as botanist to the King of France, and employed himself in acquiring a distinct knowledge of the plants and animals indigenous to that country, of which he published accounts on his return. He died November 18, 1755. In 1741, he published "A Description of the Causes of the Colour of the Skin in Negroes," which he thought was occasioned by the bile being in them bleaker than in Europeans; and in 1746, "Observations on the Origin and Formation of the Different Stones." But his principal works were "Etui fur l'Histoire Naturelle de la France Equinoctiale," Paris, 1751, 12mo. in which he gives descriptions of the plants he had collected at Cayenne, many of them not before known, with their use in medicine, diet, &c. "Nouvelle Relation de la France Equinoctiale," Paris, 1743. 12mo.; republished, much improved, 1753, a continuation of the former work. In this he gives accounts of the method of cultivating the sugar-cane, of preparing sugar, coffee, aloes, and other valuable articles. In the "Histoire de l'Academie des Sciences," 1747, the method of cultivating rice; and in 1751, at Perpignan, 8vo. "Diverses Observations anatomiques tirées des Ouvertures des Cadavres," containing some curious and instructive cachets. Haller, Bibl. Anat. et Botan. Edav. Dict. Hist.

Barreria, in Botany, a tree so named from Peter Barrere, professor of medicine at Perpignan. Lin. 1365. Supp. gen. 767. Porcupebus. Aubl. Guin. Cifas. Syngymnsa monopetala. Gen. Char. Cifas. perianth one-leaved, five-toothed, small. Cor. one-petalled, five-parted; petals oblong, acute, convex beneath, concave above, with a double tip, the superior oval, bident, the wedge-shaped one triad; excavated for the reception of the filaments. Stam. filaments five, ascending linear, wider above, thick, triangular, bordered, curved; anthers erect, four-cornered, margined, coalescing into the form of a mill-wheel; each, in the closed flower, anwering, together with the filaments, to the pits, the two petals. Fil. gern roundish; stile short; stigma trifid.

Eff. Cif. Char. Cal. five-toothed, very small. Cor. five-parted; stile short; stigma trifid.

Species. B. guian. nis. Porcupebus Guian. Anbl. Guian. t. 37. A tree forty or fifty feet high, and two feet and a half in diameter; the bark is soft coloured, and the wood is hard and compact, of a reddish brown colour. From the seeds, which are covered with numerous twigs, with alternate, entire, smooth, firm, ovate leaves, ending in a long point; petioles short, convex beneath, channelled above. The flowers are
in small auxiliary spikes, alternate, and almost sessile. A native of Guinea, in the extensive forests, near the banks of the river Sincarri, fifty leagues from its mouth. It flowers in November.

BARRET, George, in Biography, a painter of landscape, was born about the year 1752, in the city of Dublin, and exhibited at a very early age a strong disposition to the art in which he afterwards became eminent. Having gained a premium of 70l. offered by the Dublin Society for the best landscape in oil, he visited London in 1762, and in the second year after his arrival, obtained a similar prize from the Society for the encouragement of arts, &c. The establishment of the Royal Academy of Arts, &c. is said to have been much indebted to the efforts of Mr. Barret, who formed the plan, and became one of its members. He had two decided manners of painting, both with regard to colour and touch; his first was rather heavy in both, his latter was much lighter. Scarcely any painter equalled him in his knowledge or execution of the details of nature, the latter of which was particularly light, and well calculated to mark most distinctly the true characters of the various objects he represented, forest-trees in particular. His attention was chiefly directed to the true colour of English scenery, with regard to which he was very happy in his belt works. His belt pictures, in this country, executed according to his first manner, are to be found in the houses of the dukes of Buccleugh and Portland, &c. and those of his latter in his great work at Norbury Park in Surrey, confining of a large room, painted with a continued scene entirely round. The idea in general characterizes the northern part of this country; and for composition, breadth of effect, truth of colour, and boldness of manner in the execution, has not been equalled by any modern painter. Barret also excelled in water colours; and his drawings in chalk, Indian ink, and black-lead pencil, have great merit. In all his studies from nature he was very correct and minute. He also penned a fine flight but spirited etchings in landscapes. He died at Paddington near London in 1784. Pigkington and Strutt.

BARRET Bank. Great, in Geography, lies at the S. and S.E. end of the island of Oleron on the coast of France, and forms the N.W. side of the Maumelon passage, as Point de Gourdou, on the main land, forms the S.E. side.

BARETTRY. See Baratry, and Barratry.

BARRETSTOWN, in Geography, a plantation in Hancock county, in the district of Maine, in North America, having 735 inhabitants.

BARRICADE, or Barricado, a military term for a fence or retrenchment, hastily made with vessels or bales of earth, carts, trees, palisades, or the like, to preserve an army from the shot or ambush of an enemy.

The most usual materials of barricades are pales, or flanks which are croffed with battoons, and fixed with iron at the foot; usually fet up in paffages or breaches, to keep back the houfe as well as the foot.

BARRICADE, in the Marine, is a strong wooden rail, supported by pillars, and extending as a fence across the foremost part of the quarter deck. In ships of war, the intervals between the pillars are commonly filled with cork, junks of old cable, or painted cordage. About a foot above the rail, there extends a double rope netting, supported by cramps of iron; and between the two parts of the netting are fluffed hammocks, filled with the seamen's bedding, to intercept small shot fired by swivel-guns and mufkets, in time of battle.

BARRICOURT, in Geography, a town of France, in the department of the Ardennes, and chief place of a canton in the district of Grandpré, 6 leagues S. of Sedan, and 5 N.E. of Grandpré.

BARRIER, in Fortification, a kind of fence made at a passage, retrenchment, gate, &c. to keep the enemy from entry thereof. See Defence. It is usually made of great flakes about four or five feet high, placed at the distance of eight or ten feet from one another, with overhanging rafters; having to stand either horse or foot that would rush in. In the middle is a moveable bar of wood, which opens and shuts at pleasure.

BARRIER Islands, in Geography, islands which lie off the river Thames, on the E. coast of New Zealand, and so called because they shelter it from the sea. They stretch from S.E. to N.W. for 10 leagues.

BARRIERS, corresponding to what the French call, "jeu de barres," i.e. palisades, have been used to signify a martial exercise of men, armed, and fighting together with short swords, within certain rails or bars, by which they were inclosed from the spectators; now diffused in this country.

BARRIES, or BARRIERS, a name given, in the chief cities of France, and particularly at Paris, to the places where the custom-houses are established, and where the officers receive the duties of importation, according to the tariff settled by the king's council. They are called barriers because the palisades, through which the carriages and merchandises liable to pay duties are to pass, are shut up with a wooden bar, which turns upon a hinge, and is opened and shut at the will of the custom-house officers.

There are at Paris sixty of these barriers, all placed at the entrance of the suburbs.

There are also barrier town, or places of defence, on the frontiers of kingdoms.

BARRILE, in Geography, a town of Italy, in the kingdom of Naples, and province of Bari, 7 miles W.S.W. of Venice.

BARRING a Vein, in Farriery, now obsolete. See Bar a Vein.

BARRINGDIN, in Geography, a town of Africa, in the country of Bara.

BARRINGTON, John Shute, Lord Viscount Barrington, in Biography, a learned nobleman, particularly distinguished by his attention to theological subjects, was the youngest son of Benjamin Shute, merchant, by a daughter of the famous Mr. Caryll, author of the commentary on Job, and descended from the ancient family of Shute in the county of Leicester, of Roman extraction. He was born at Theobald's in Hertfordshire, in 1678, and received part of his education in the university of Utrecht. Upon his return to England he devoted himself to the study of the law in the Inner Temple; and in 1701 commenced his literary career as a writer, if we except his Latin oration "De Studio Philosophiae coniungendo cum Studio Juris Roman," published at Utrecht in 1698; by an "Effay upon the Interests of England in respect to Protestants dissenting from the Established Church." 40. to which class of British subjects he belonged. This was followed some time afterwards by another piece in 4to, intitled "The Rights of Protestant Diffenters, in two parts." At the age of 24, during the prosecution of his legal studies, he was appointed by the recommendation of lord Somers, to the arduous undertaking of engaging the Presbyterians of Scotland to favour the union of the two kingdoms, and in 1708 he was rewarded for his services by the office of commissioner of the customs. From this situation he was removed by the Tory administration of queen Anne, in 1711, on account of his avowed opposition to their principles and conduct. In the mean time his fortune was greatly improved by the bequest of two considerable
floribite states; one left him by John Wildman, Esq. of
Becket in Berkshire, who adopted him for his son after the
Roman extinction, and the other by Francis Barrington, Esq.
of Tofts, whose name and arms he assumed by act of par-
liament. On the accession of George I. he was chosen
member of parliament for the town of Berkswich upon
Tweed; and in 1720 he was advanced by the king to an
Irish peerage under the title of Viscount Barrington of
Amblesie. In consequence of his unfortunate connexion
with the Hanbury company, as full-governor under the prince
of Wales, and of a lofty project for defraying the expense
of opening the port, and a full permission for this purpose
commenced during his residence in opposition to his opinion and
advice, he withdrew in 1723, the very severe and imminent
decree of expulsion from the house of common, which has
been attributed to his lordship's opposition to the reigning
minister, for Robert Wipole. In 1725, he published in two
volumes 8vo his "Miscellanea Sive, or a new method of
countering to much of the history of the popes as is con-
tained in scripture, in an abstract of their history, an abstract
of that abstract, and four critical essays." This work traces,
with judicious discrimination, the methods taken by the
popes, and first preachers of the gospel, for propagating
Christianity, and explains the several gifts of the spirit by
which they were enabled to discharge that office. Hence he
deduced an argument for the truth of the Christian religion
which is said to have staggered the inconstancy of Mr. Anthony
Collins. A second edition of this work, with large additions
and corrections, was published by his son the present bishop
of Durham, in 1727, 3 vols. 8vo. In the interval between
its first publication and the death of the author in 1734,
he reviewed, corrected, and enlarged it; and introduced
such improvements, as add new force to his arguments and
climations to his critics. In the same year, 1735, he
also published "An Essay on the several Dispositions of God
to Mankind, in the order, in which they lie in the
Bible, or a short system of the religion of Nature and
Scripture." He was also the author of several other tracts,
chiefly on subjects connected with toleration in matters of
religion, which he ably and zealously defended. He died
in 1734, in the 56th year of his age. Lord Barrington
had three daughters and five sons, five of whom have been
advanced to high stations in the church, the law, the
army, and the navy. His lordship was a disciple and friend to
Mr. Locke, and adopted his sentiments as to the right and
advantage of free inquiry, and the value of civil and reli-
gious liberty. As a theological writer, he discovers a high
fealty of the value of the sacred writings and great judgment
in interpreting them; and he contributed in a very eminent
degree to the diffusion of a spirit of liberal criticism. In
his sentiments and dispositions he was distinguished by his cath-
olicism and moderation; and though he was a rational and
studious diverter, he was an occasional frequenter and commu-

Barrington, Daines, the fourth son of lord Barrin-
gton, was educated for the profession of the law, and in 1757
was appointed a Welsh judge, and some time afterwards sec-
ond judge of Chettir. Although he never attained to
his distinguished eminence at the bar, he evinced his acquain-
tance with the law by a valuable publication, entitled, "Ob-
ervations on the Statutes, chiefly the more ancient, from
Magna Charta to 21 James I. c. 27; with an Appendix
being a proposal for new-modelling the Statutes," fol.
1760. This work, which passed through five editions, has
been respectfully quoted by many historians and consti-
tutional antiquaries. In 1773, he published "Oro"as, with
Alfred's Saxon version, and an English translation and notes
of his own, which underwent a severe amendment from
the substance of our critics. His "Tracts on the Probability of
reaching the North Pole," 1773, 4to, were occasioned by the
voyage of captain Philip (now lord Mulgrave) towards
the north pole in 1773. His other writings may be found in the
Tracts of the Royal and Antiquarian Societies, of
which he was an ardent member, and of the latter vice-
prestident. In several of these the author manifests some
tendency towards singularity and paradox; nevertheless they
indicate both diligence and extent of research, and evince
his talents as a naturalist and antiquarian. Many of
his tracts were collected by himself in a 4to volume, entitled
"Miscellaneous Tracts on various subjects," 1781. His ex-
periments and observations on the fungus of birds" (see Sons
of Birds in this Diction.ary), and his "Essay on the
Language of Birds" are amongst the most curious and in-
genuous of his papers. In private life he was a man of worth
and integrity, unambitious, and devoted to study and liter-
ary conversation. He resigned his office of justice of Chettir
in 1755, and from that time to his death, March 14, 1800,

Barrington, in Geography, a township in Queen's county
Nova Scotia, on the south side of the bay of Fundi, settled
by Quakers from the island of Nantucket.

Barrington, a township in Strafford county, New
Hampshire, about 22 miles N.W. from Portsmouth, in-
corporated in 1722, containing 2470 inhabitants. Alum is
found in this township, and the first ridge of the "Froth-
hill," one of the 3 interior summits of Agamenticus, is
continued through it. Its situation is very healthy, and fa-
vourable to longevity.

Barrington, a township in Bristol county, Rhode
island, on the south western side of the N.W. branch
of Warren river, about 24 miles N.W. of Warren, and about
7 S. E. from Fox point, in the town of Providence. It
contains 682 inhabitants, including 12 slaves.

Barrington, Great, is the second township in rank in
Berkshire county in the Massachusetts. It contains 1373
inhabitants, and lies 1: 40 miles W. from Boston.

Barrington, Cape, is the south-east point of lord Eg-
mont's island, or New Guernsey, the largest of the Queen
Charlotte's islands. It is separated by a narrow channel
from Cape Poly, on lord Howe's island, or New Jersey.

Barringtonia, in Botany, a beautiful tropical tree named
by Forster from the Hon. Daines Barrington. Lin. g. S.hreb.

Gen. Char. Cal. Perianth two laved, superior; leaflets
roundish, concave, coriaceous, permanent. Cor. Petals four,
equal, ovate, spreading, coriaceous, larger than the calyx;
nectary cone, tubular, clothed the base of the style, toothed
at the tip; teeth several, unequal. Stam. Filaments very
many, monadelphous, or (conjoined from the very base into
a cylinder seated on the receptacle), capillary, larger than
the corolla; anthers small, roundish. Fil. Germ inferior,
turbinate; style filiform, length of the flaments; stigma
fimbrious. Per. Drupes large, ovate, conic-quadangular,
crowned by the calyx. Seed, nut long, ovate, outwardly
wrinkled-fibrose, four-celled; kernels ovate, wrinkled.
Eff. Gen. Char. Cal. Simple, two leaved, superior, per-
manent; fruiit a dry four-corned drupe, including a
nut to four-celled.

BARRISTER, the name given to an inferior judge established in every county of Ireland, except that of Dublin, whose business it is to sit twice every year to try civil bills, for the more speedy administration of justice.

BARRITUS, in Antiquity, a military shout raised by the Roman soldiers at the first charge on the enemy. This custom, however, was not peculiar to the Romans; but prevailed among the Trojans according to Homer. Among the Germans, the Gauls, the Macedonians, and the Perths. See Classicum.

BARROCHES, in Geography, are two great ranges of rocks close by the west end of Alderney, Avigny or Orany, towards the Caskets.

BARROS, John Dos, in Biography, an eminent Portuguese historian, was born at Vilaça, in 1496, and educated at the court of king Emanuel, with the royal children. In 1522 he was appointed to the government of St. George del Mina, on the coast of Guinea; and upon his return to Portugal, after an absence of three years, he was made treasurer of the Indies. When King John encountered upon him the lordship of Paraisa in Brasil, on condition of his expelling the native Indians, and peopling it with Portuguese, he set out with an expedition for this purpose; but his fleet being almost wholly destroyed, the project failed. Upon this he determined to write the history of the Indies, under the title of "Decades d'Alia;" and the first decade was published in 1552, the second in 1553, and the third in 1553. For the completion of this work he retired to Pompal, where he died in 1570, leaving several children. His fourth decade, compiled from his MSS. by order of Philip III. did not appear till 1645. The work has been continued by others as far as the thirteenth decade; and the last edition of it was printed at Lisbon in 1756. 3 vola. folio. The history of dos Barros, applauded by fome and ceniled by others, is deemed, notwithstanding the author's disposition to exaggerate, a work of authority. It was translated into Spanish by Alphonsus Ulloa. Barros was the author of several other writings, moral, grammatical, &c. composed principally for the use of his pupil prince John, fon of king John III. In some editions of his "Decades," there is an an apology for his life and writings, written by himself. Moreen. Nom. Diet. Histor.
nobleman under his care. In 1643, he was admitted a pen-
sioner of Peter-houfe in Cambridge, under his uncle Mr.
Izaac Barrow, afterwards bishop of St Alphat, and then
d fellow of that college; and in 1645, he was entered a pen-
sioner of Trinity college, as his uncle had been elected
together with others that had written against the covenant.
The ejection of his uncle, and the latter fulfilled by his
father on account of his attachment to the royal cause,
involved our young fludent in difficulties; and he was in-
deleted to the liberality of Dr. Hammond for his chief sup-
port. Such were the sweetness of his disposition and his
respectful conduct towards his superiors, that he preferred
their esteem and good-will, though he readily adhered to the
cause for which his family had suffered and refused to take
the covenant. His proficiency in all branches of literature,
and particularly in natural philosophy, was fo considerable,
and his merit so generally acknowledged, that he was elected,
notwithstanding the obnoxiousness of the party to which
he belonged, fellow of his college in the year 1649; and
now perceiving that the circumstances of the times were
unsavourable to persons of his opinions in matters of church
and state, he determined to devote himself to the
medical profession. With this view he directed his at-
tention to anatomy, botany, and chemistry, and made
some progress in these preparatory studies; however, upon
further consideration, aided by his uncle’s advice, he resumed
the study of divinity in connection with that of mathematics
and astronomy. With the fewer studies he also blended the
amusements of poetry, to which he had a strong propen-
sity. In 1652 he commenced master of arts, and was in-
corporated in that degree at Oxford. Dis appointed with
regard to the Greek professorship at Cambridge (to which
he was recommended) on account of a suspicion of his Ar-
menian principles, and perhaps influenced by the aspect
of public affairs, he resolved to travel abroad; and in order to
obtain a necessary supply for this purpose, he sold his books.
Accordingly he set out in the year 1655; and in this year
his first work, which was an edition of ‘Euclid’s Elements,’
was published during his absence. He visited France and
Italy; and in 1656 he set sail from Leghorn to Smyrna;
and in the course of his voyage he had an opportunity of
manifesting his natural intrepidity by flouting to his
gun, and defending the ship on which he had embarked,
avoid the attack of an Algerine corsair, and of beating off
the enemy. Of his intrepidity, as well as bodily strength,
another instance occurred on a very different occasion. As
he was once leaving the house of a friend early in the morn-
ing before a fierce maffiff was chained up, the dog flew
at him with violence; but he had the resolution to frize
the dog by the throat, and after much struggling to over-
power him, and to hold him fast on the ground till some
of the domestics rose and parted them. From Smyrna he
proceeded to Constantinople, where he read over with pecu-
liar satisfaction the works of St. Chrysostom, the bishop of
that place; and having remained a year in Turkey, he re-
turned to Venice, and in 1659 passed through Germany
and Holland into England. Soon after his return he was
ordained by bishop Brownrigg; and when the king was
restored, his friends expected that his attachment to the
royal cause would have been rewarded by some consider-
able preferment: but their expectations were disappointed.
On this occasion Barrow wittily remarked in one of his
poems:—

"Te magis optavit reditum, Carole, nemo, 
Et nemo fequit te reditu minus;"

"Thy restoration, Royal Charles, I see,
By none more with’d, by none less felt, than me."

Vol. III.

However, he wrote an ode on his majesty’s restoration,
in which he introduces Britannia congratulating the king
upon his return. In this same year, 1660, he was chosen
Greek professor at Cambridge; and in consequence of this
appointment, he read lectures on the Rhetoric of Aristotle.
In 1662 he was recommended by Dr. Wilkins, and elected
to the professorship of geometry in Gresham college; and he
also discharged the duty of the astronomical professor,
who was absent. About this time he declined a valuable
preferment which was offered him, from scruples of con-
science; because it was annexed to the condition of educa-
ing the patron’s son, which Barrow considered as a kind of
financial contract. In 1663, he was included in the first
choice of members made by the Royal Society after re-
cieving their charter; and in the same year he was ap-
pointed Lucasian professor of mathematics at Cambridge,
on which occasion he delivered an excellent oration on the ex-
cellence and use of mathematical science. At this time he re-
signed both his Greek and Gresham professorships. Although
the baron to which he had attained was peculiarly adapted
to his distinguished talents and acquisitions as a mathema-
tician, he determined in 1669 to exchange his mathematical
studies for those of divinity; and accordingly, as soon as he
had published his ‘‘Lectiones Opticae,’’ he resigned his
professor’s chair to the illustrious Newton. In 1670 he
was created doctor in divinity by mandate; and in 1672 he
was nominated to the mastership of Trinity college by the
king, who observed, ‘‘that he had bow’d it on the ball schollar
in England.’’ To the patent of his appointment was annexed a clause which allowed him to marry; but as
this privilege was inconsistent with the statutes of the col-
lege, he infil’d on the clause being erased. On this oc-
casion he resigned the preferments of a small procure in
Wales, and of a prebend in the cathedral of Salisbury, which
he had previously enjoyed and the profits of which he had
distributed to charitable uses. In 1673 he was chosen vice-
chancellor of the university; but his services in this high
and honourable station were speedily terminated by his
death, occasioned by a fever, in London, May 1677, in the
47th year of his age. His remains were interred in Well-
minster Abbey; and a monument, with an appropriate epi-
taph, was erected for him at the expense of his friends.
Dr. Barrow had nothing in his person or external appearance,
that was likely to command any degree of attention and
respect. He was of a low stature, and of a meagre, pale
aspect; and he was singularly negligent with regard to his
dress. Pope, his biographer, mentions a circumstance to
this purpose, which shews the effect of his inattention to
outward appearance. Being engaged to preach for Dr.
Wilkins at St. Lawrence Jury in London, his slovenly and
awkward gilt and meagre aspect prepossessed the audience
so much against him, that, when he mounted the pulpit, the
congregation withdrew, and he was left alone in the
church. Mr. Richard Baxter, the nonconformist div-
ine, however, was one of those few that remained; and
his testimony was highly honourable to the preacher, for he
declared that he had never heard a better sermon, and that
he could with pleasure have listened all day to such preach-
ing; upon which those persons who complained to Dr.
Wilkins of his subtiltute were ashamed of their conduct in
deferring the church, and reduced to the necessity of ac-
knowledging that their prejudice was solely the result of
his uncouth appearance. His sermons were distinguished
not only by their excellence, but by their length. He took
great pains in composing them, and in transcribing them
three or four times, as he found it extremely difficult to
please himself. M. Le Clerc (Biblioth. Univ. t. iii. p. 325.)

4 X
B A R R O W.

To the public, gentlemen and ladies, who have been pleased to observe the late Mr. Barrow, in his public capacity, this present book will improve their esteem, and confirm them in their good opinion of his abilities and integrity.

Introduction.

The late Mr. Barrow, after having for many years excelled in the higher branches of learning, and having made himself conspicuous as an instructor in the schools, has, in the year 1655, published a collection of his lectures on the optics, under the title of "Lectiones Opticae XVIII.; Cantabrigiae in scholis publicis habite," etc., London 1659, 4to.; this work was revised and enlarged by Newton, and has been highly commended by the best judges. "Lectiones Geometricæ XIII. in quibus praebetur demonstratio generalis linearum curvarum symptomatis declaratur!" London 1670, 4to.; published in 1672 and 1674, with the "Optics." "Archimedes Opera; Apollonii Conicorum Libri IV.; Theodoci Sphæricæ, methodo nova illustrata, et faciencie demonstrata!" London 1675, 4to.; After Dr. Barrow's decease, were published his "Lectio in qua theologorum Archimedes de Sphæra et Cylindro, per methodum indivisibilium inventi, ac breviter demonstrata, exhibentur!" London 1678, 12mo.; and "Mathematicæ L.-Gentis, habitæ in scholis publicis Academiae Cantabrigiensis!" London 1683, 8vo. Besides these, Dr. Barrow left several curious papers, written with his own hand, and communicated to William Jones, etc., to Dr. Ward. Ward's Lives of the Professors of Gresham College, p. 157, etc. Dug. Brit.

Barrow, in Geography, a noble river of Ireland, supposed to be the Blegum Brugia of Ptolemy. It rises in the mountain of Slepp B'oom in the King's county, and running for a short space north east, makes a kind of elbow; and continuing afterwards a south west course, it divides the King's and Queen's counties from that of Kildare. At Athy, in the latter county, a branch of the grand canal from Dublin to the Shannon has formed a junction with it; which contributes much to the advantage of the adjoining county. It proceeds next through the heart of the county of Carlow, and then separates those of Kirkkenny and Wexford. A little before it reaches the town of Ros, it receives the Nore, and then varying its course somewhat to the west, minglest its waters with those of the Suir, forming with it the haven of Waterford. The navigation of this river has been deemed of such great importance that 2,600 pounds have been granted by parliament to remove some obstructions in it; and a corporation established for the purpose has been enabled to raise 20,000l. more to render it completely navigable. It is now (182-2) expected that boats will soon regularly ply from Waterford to Athy, and then by the grand canal to Dublin. The circumstance of the three rivers, Barrow, Nore, and Suir, all rising in the same mountain, proceeding from it by different courses, and uniting their streams before they fall into the sea, has been mentioned by many writers. Amongst others, Spenser has noticed it in his epistle of the marriage of the Thames and Medway (Fairy Queen, book iv. cant. 11); in which he represents them as three brothers, sons of the giant Diomus and the nymph Rheusa. He speaks of the Barrow as abounding in salmon:

"The third, the goodly Barrow which doth hound Great heapes of salmon in his deeps beforeme."

Campbell's Political Survey, &c. &c.

Barrow, Little, a river of Ireland, which runs into the Barrow, about four miles E. of Portarlington.

Barrow Harbour is an extensive bay in that of Bonavista in the island of Newfoundland, divided by Keel's head on the E. from the port of Bonavista, and from Bloody bay on the W. by a large peninsula joined to the island by a narrow isthmus, which forms Newman's found; which, as well as Cloghe found, are within Barrow harbour.

Barrow Point, a cape on the south coast of Ireland, in the county of Cork, 5 miles east of Kinsale.

Barrows, or Tombs, in Topography, a name usually given to those hillocks or mounds of earth which were apparently

fays of them, that they were trivial or exact disquisitions rather than harangues to please the multitude; and Dr. Tillotson, who published them, observes in his preface, that "their own elegance and eloquence will prove them better;" and king Charles II. used facetiously to call him "an un-
Barrow.

ciently raised over the bodies of deceased heroes and persons of distinguished character. This mode of interment may be traced to the remotest antiquity, and instances of it occur in all quarters of the world. A learned antiquarian, well known for his indomitable and indefatigable research (see Geth's Sepulchral Monuments of Great Britain), confers barrows as the most ancient sepulchral monuments in the world. Homer describes the embankment which contained the construction of barrows in describing the funeral rites attended by the interment of Patroclus and Achilles. The body of Patroclus was laid on the top of a great pile of wood about one hundred feet square, and covered with the fat of animals offered in sacrifice, the carcases of the beasts, and the bodies of the Trojan captives cruelly slain in cold blood on the occasion, were then thrown on the pile round its edges, and the whole reduced to ashes. The remains of the fire were next day extinguished by pouring wine on the embers; and as many fragments of the bones of the deceased as could be collected, were wrapped up in fat, and put into a rich urn, having a linen veil flung over it. The whole army then threw earth upon the spot where the urn had been committed, so as to cover the bones of the Trojans, of the beasts, and all the ashes that remained, and then reared a high rude hill, under which, nearly in the centre, the urn was placed. After this ceremony, solemn games were performed, and chariot races were exhibited round the barrow, in honour of the deceased. To this purpose, the elegant translator of Homer, in his account of the funeral of Patroclus, expresses part of the funeral ceremony:

"High in the midst they keep the dwelling bed Of rising earth, mortal of the dead."

Iliad, xxiii. 310.

In Plutarch's Life of Alexander, we find that when that great conqueror arrived at the ruins of Troy, he anointed with much ceremony the stone placed on the barrow of Achilles, purged out libations, and, as the custom was, ran naked round the sepulchre, and crowned the stone with garlands.

Herodotus, the father of history, mentions the barrow of Alyattes, the second of that name, king of Lydia, and father of Croesus, raised 2505 years ago, and seen by Dr. Chandler in A. D. 1794, five miles from Sard, the ancient Sardis. This tumulus or barrow, formed by the joint exertions of the merchants, the labourers, and the prostitutes, was about a mile in circumference, 1300 feet broad, and terminated by a piece of water called the Gygean lake, still remaining. Dr. Chandler, in his "Travels through Asia Minor," vol. i. p. 42, describes this and other barrows in their present state; and Herodotus states, that the lower part of it was a mass of large stones, but that the rest of the sepulchre was a tumulus of earth.

It is customary among the Greeks to place on barrows, either the image of some animal: or tomb, termini, or round pillars with inscriptions. Pausanias describes the famous barrow of the Athenians in the plain of Marathon, on which were pillars of this kind; and on that of Alyattes were five stones, on which were engraved letters, denoting how much each clod of the persons concerned had performed towards it, and it appeared that the greater portion was done by the young women. An ancient monument in Italy, near the Appian way, called without reason the sepulchre of the Curtii, has the same number of termini with that of Alyattes, the base, which is square, supporting five round pyramids. We are informed in the scriptures, that when the king of Ai was slain by Joshua, his carcase was placed at the entrance of the city, and upon it was raised a great heap of stones. Several other passages of the sacred writings lead us to conclude, that though the Jews were prohibited from adopting such funeral customs of the Gentiles, they did not think themselves restrained from erecting these monuments to their deceased relatives. Diodorus Siculus, speaking of the Buliines, says, that after piling together the limbs of a dead body with stone, they cast it into a hollow receptacle, and placed over it a large heap of stones. Virgil alludes to this mode of interment as used in Italy in the times to which the Aenid refers. Xenophon relates that it obtained among the Persians; the Roman historians record it as taking place among their countrymen; and it prevailed no less among the ancient Germans, Britons, and other nations.

According to Herodotus, the Geri, a people of Scythia, raised barrows; and the custom of erecting them in various parts of the world continued through a long series of ages. Gough says, that they continued in use till the 14th century.

The ancient barrows are of various sizes; some of them being small, and perhaps designed for children, or the younger branches of the royal family; or for persons of meaner rank; others distinguished by their height and bulk, and built like hills at a great distance, which might probably have been the sepulchre of some renowned monarch or warrior, or general burying-places.

Stadelberg, in his description of the northern and western parts of Europe and Asia, informs us, that great numbers of tumuli, called by the Russians "borghi," are found in Siberia, and in the deserts which border on that country towards the north; and that in these tombs are found many plates, ornaments, and trinkets of gold. Some of them are raised by earth as high as houses, and appear in the distant plains like a ridge of hills; whilst others are set round with rough-hewn stones. Archaeologia, vol. ii. p. 230.

The custom of interring with the dead their arms, their jewels, and sometimes their horses and servants, is traced by M. Legrand D'Auffy (Mem. de l'Institut, National des Sciences, &c., Paris, vol. ii.) to the mythology of the northern Asiatic nations, which taught them to believe that they should make an appearance in another world, corresponding to the ornaments and attendants deposited in their tombs; and the remains of this superstition have descended through many ages. According to this writer, a great part of the riches acquired by the northern nations in their irruptions, has been interred in the tombs of the conquerors. Tracusses have been frequently found in the barrows so common in Tartary; and, in attempting to ramshack these monuments, the Siberians have had so many conflicts with the Tartars, that the Russian government has been obliged to put a stop to their researches.

Denmark, Sweden, Lower Saxony, and many other countries on the continent, abound with sepulchral monuments of this kind. Mr. Cox, in his "Travels in Poland," (vol. i. p. 130) mentions two large barrows in the vicinity of Cracow; one by tradition called the burial-place of Casimir, duke of Poland, who is supposed to have built the town in the year 720; and the other called the sepulchre of his daughter Venda, who is reported to have drowned herself in the Vistula to avoid a marriage with a person whom she detested. As popular tradition records these as favourite characters in their country, it has honoured them with interments under the most conspicuous of these monuments called barrows.

The barrows of England are very numerous scattered over the plains of Wiltshire, the downs of Dorsetshire, Kent, and Surrey. Monuments of the same appropriation
BARROW.

are also abundant in the northern counties of England, North Wales, Scotland, and Ireland; but most of these consist of vast piles of stones and are designated by the name of "carn," or "cairi." (See Carn.) The most considerable barrow in England is that of Silbury Hill in Wiltshire. (See Axbury.) A barrow in Derbyshire, situated on the summit of a hill called "Fin-cop," has been carefully investigated by Mr. Hayman Rooke. (See Archaeology, vol. x.) It differed two or three feet in height, one of which had an oblong piece of dressed black Derbyshire marble fastened by a strong cement to the skull: some urns also appeared, with ashes and burnt bones, together with arrow-heads of flint, and a spear-head shaped out of a piece of lime-stone, and made very sharp at the point. Mr. Rooke conjectures, that this elevated spot, secured by a double fence, may have been the site of a Briton town or fortresses, and that the barrow was the sepulchre of the chieftain and his relatives; the weapons of flint and of lime-stone undoubtedly suggested a very remote period, and, when found as they were, appear to indicate the relics of a primitive and barbarous people. Dr. Plott takes notice of two sorts of barrows in Oxfordshire, one placed on the military ways, the other in the fields, meadows, woods, &c.; the former he supposed were of Roman erection, and the latter were more probably erected by the Britons or Danes. Some of these barrows appear rude and constructed only of earth; others are more regular, and trenchèd round, some of them with two or three circumvallations, and surmounted with monumental stones. (Platt's Nat. Hill. Oxfordshire, ch x. s. 4.) We have an examination of the barrows in Cornwall by Dr. Williams, in the "Philosophical Transactions," No. 458; from whose observations we find that these barrows are composed of foreign or adventitious earth; that is, such as do not occur on the spot, but must have been fetched from some distance. In one of them was found an urn made of burnt or calcined earth, very hard, and very black within; it had four small handles, and in it were found seven quarts of burnt bones and ashes. As it was the ancient practice to burn the dead, it appears from these barrows, how the people that used this mode of burial expressed their respect for the dead; it was by erecting over them these tumuli or barrows, composed of earth or stone brought from distant places; and the barrow was generally proportioned to the rank and power of the deceased person.

Each fowler, or friend, might bring some of the earth or stones from distant places where they lived, and thus compose the tumulus. Many passages might be quoted from ancient authors to this purpose. The contents of these barrows, as well as their size and form, have been very various: in some have been found stone chests containing entire urns; and in others, bones neither lodged in chests nor deposited in urns: arms of various sorts, amber beads, &c. have not been uncommon.

The links or fends of Skail in Sandwich, one of the Orkney islands, abound in round barrows, some formed of earth alone, and others of stone covered with earth. In the former was found a coffin made of a flat stone, and as it was too short to receive a body at full length, the skeletons had their knees folded to the breast, and the legs doubled along the thighs. A bag made of rushes has been found at the feet of some of these skeletons, which contained the bones, probably, of another person of the same family. In one of these were discovered multitudes of small beetles; and as similar insects have been found in the bag which enclosed the sacred Ibis, it may be supposed that the Egyptians, and the nation to which these tumuli belonged, might have had the same superstition respecting them. Some of the corpses interred in this island appear to have been burned; as the ashes deposited in an urn which was covered with a flat stone, have been found in the cell of one of the barrows. This coffin, or cell, was placed on the ground, then covered with a heap of stones, and cased with earth or sods. This barrow and its contents evince them to be of a different age from the former. These tumuli appeared to be a kind of family vaults, two tiers of coffins having been found in them; and it is not improbable, that on the death of any one of the family, the tumulus was opened, and the body interred near its kindred bones.

Barrows are very numerous in Ireland. Ledwich supposes them to have been of Scythian origin, and to have been introduced in Britain after the Romans had left it. It was a law of Odin, the great Gothic legislator, that large barrows should be raised to perpetuate the memory of celebrated chiefs; these were composed of stone and earth, and were formed with great labour and stone art. At New Grange in the county of Meath is a mound of this kind, the altitude of which from the horizontal floor of the cave is about 70 feet, the circumference at the top is 300 feet, and the bale covers two acres of land. It is founded on an astonishing collection of stones, and covered with gravel and earth. In the "bren-teid," or fiery age, which was the first among the Northerns, the body was ordered by Odin to be burned with all its ornaments, and the ashes to be collected in an urn and laid in a grave; but in the "hoelt-tiid," or age of hillocks, being the second, the body, untouched by fire, was deposited in a cave or sepulchre under a barrow; and this mode was practised till the third epoch, called "chribendoms-old," or the age of Christianity. Governor Pownall, who has given an account of New Grange, in the second volume of the "Archaeology," observes, that the mode of burial, and the species of sepulchral monument at New Grange, may be traced through Denmark, Sweden, Russia, Poland, and the Steppes of Tartary; and he conjectures that this mound was a Danish work; which was also the opinion of Sir Thomas Molyneux, M. D. in his "Essay on Danish Mounts," published with "Boaste's Natural History of Ireland." About 1699, a Mr. Campbell, who resided in the village of New Grange, observing stones under the green sod, carried many of them away, and at length arrived at a broad flat stone that covered the mouth of the gallery. At the entrance, this gallery is 2 feet wide and 2 high; at 13 feet from the entrance, it is but 2 feet 2 inches wide: the length of the gallery, from its mouth to the beginning of the dome, is 62 feet; from thence to the upper part of the dome, 11 feet 6 inches; the whole length being 71 ½ feet. The dome or cave, with the long gallery, exhibits the exact figure of a crofs, the length between the arms of which is 20 feet: the dome forms an octagon, 20 feet high, with an area of about 17 feet; it is composed of long flat stones, the upper projecting a little below the lower, and closed in and capped with a flat flag. There are two large oval rock basins in this cave, one in each arm of the crofs; from which, and the cruciform shape of the structure, it is supposed to be the work of semi-Christian Oldmen in the ninth century. The custom of burying the treasure acquired by piracy, in the barrows of great men, accounts for the Roman coins found at New Grange. For a more particular account, the reader is referred to Mr. Ledwich's Antiquities of Ireland, p. 307—328. General Vallancey, however, and other antiquaries, consider this cave at New Grange to have been "a sanctum Mithraeum," or a cave for the worship of the sun, introduced by
by the Perfo-Scythic colony, which they suppose to have come to Ireland from Spain, and to have established the customs of the eastern nations.

Tumuli or barrows are also found in great numbers in America; and the American Indians are said to practice a similar mode of burial at this time, generally depositing, with the bodies the implements of war and agriculture used by the deceased. Mr. Jeffeson, in his "Notes on the State of Virginia," p. 156, has given a particular account of the American barrows. They are of different sizes, and formed of different materials; some of earth, and some of loofe stones. That they were repositories of the dead is generally allowed; but the particular occasion on which they were constructed has been a subject of discussion. Some have thought that they covered the bones of those who fell in battles fought on the spot of interment. Some ascribe to them a custom prevalent among the Indians, of collecting at certain periods all their dead, wherefore deposited at the time of their death. Others again have supposed that they were general sepulchres for towns, conjectured to have been situate on or near those grounds; and this is an opinion that has been supported by the quality of the lands in which they are found, those constructed of earth being generally in the fossetl and most fertile meadow grounds, on the sides of rivers; and also by a tradition descending from the aboriginal Indians, which reports, that when they settled in a town, the first person who died was placed erect, and in this posture covered and supported by earth; that another died, a narrow passage was dug to the first, the second reclining against him, and the cover of earth replaced, and so on. Mr. Jeffeson examined one of these barrows, situate in his own neighbourhood, on the low grounds of the River, opposite to some hills on which had been an Indian town; and has particularly described its form, which was spheroidal; and also its contents, which were collections of human bones in a disjointed and scattered state. This barrow, he conjectured, might have contained a thousand skeletons. The circumstances which he has recited militate against the opinion that it covered the bones only of persons fallen in battle; and against the tradition, which would make it the common sepulchre of a town, in which the bodies were placed upright and touching each other; and indicate, that it has derived both origin and increace from the customary collection of bones, and the deposition of them together. But in what way ever this tumulus was formed, it seems to have been well known to the Indians; a party of whom, some years ago, proceeded through the woods directly to it, without any inquiry; and having remained near it for some time with expressions of sorrow, they returned to the high road, from which they had departed about six miles for the purpose of this visit, and then pursued their journey. There are many other similar barrows in other parts of the country. For further particulars relating to sepulchral monuments of this kind, we refer to Gough's Sculpchral Monuments of Britain; Douglas's Nennia Britannica; King's Monumenta Britannica; Archæologia, vol. ii. & xii.; and Britton's Beauties of Wiltshire, vol. ii.

Barrows, in the Salt Works, are cafes made with flat eft wickers, in the shape almost of a sugar-loaf, with the bottom uppermost, wherein the salt is put as it crops, and set to drain. Phil. Trans. No. 53. p. 1055. Houghton. Collect. No. 211. p. 81.

BARROWBY, WILLIAM, in Biography, son of Mr. William Barrowby, a physician of considerable repute and eminence in London. At a proper age he was admitted of Emanuell college in Cambridge, and in 1733 took his degree of Bachelor in Medicine. Soon after, he was made fellow of the Royal College of Physicinn in London, and one of the physicians to Bartholemew's hospital. He died suddenly, after eating a hearty meal, December 20, 1752, being only forty-two years of age, and then in great practice. There is a fine print of him, engraved in mezzo into by Miller, after a painting by Hayman, his father, who survived him, died October 17th, 1738, being then senior member of the College of Physicians. Our author published, in 1737, a translation into English of Afinus's treatise "De Morbo Gallico," London, 2 vols. 8vo. Eloy. Diet. Hill.

BARROWISTS, in Ecclesiastical History. See Brownites.

BARRULET, or BARRELET, in Heraldry, signifies a diminution of the bar, consisting of its fourth part.

BARRULY denotes the field of the shield of arms, when it is divided bar-ways into many equal parts.

BARRY, EDWARD, in Biography, a native of Dublin, received his medical education at Leyden, under the celebrated Boerhaave, and was created doctor of physic there in 1719. After practicing some years at York, he went to Dublin, and was made professor of medicine in the university of that city, first physician to the army there, and fellow of the Royal Society in London. In 1727, he published "A Treatise on a Consumption of the Lungs, with a previous account of nutrition, and of the structure and use of the Lungs," 8vo. London, in which he maintains the doctrine of his preceptor. To the third edition of this work, enlarged and improved, published 1759, he gave the title of "A Treatise on the Three Digestions and Discharges of the Human Body, and the Disease of their principal Organs." Haller. Bib. Anat. Eloy. Diet. Hill.

BARRY, GERALD, commonly called Geraldus Cambrensis, i.e. Gerald of Wales, in Biography, a writer of the twelfth century, was born near Pembroke in South Wales about the year 1146, and defended from a noble family allied to the princes of the country. After an early education at home, he was sent for further improvement to France, where he obtained great reputation for his proficiency in the rhetoric of the age in which he lived. Upon his return in 1172, he obtained several ecclesiastical preferments, of which the principal were the archdeaconry of Brechin, and the canony of Hereford. As he was active in church affairs, he acquired a reputation which induced the chapter of St. David's to elect him bishop of that see at the age of 30 years; but as he had reafn for apprehending the jealousy of king Henry II., he declined this ecclesiastical dignity. However, he was mortified by being under a necessity of refusing what was the great object of his ambition; and in order to divert his chagrin, he visited France; and at Paris he pursued his study of civil and canon law, and of divinity, with such success that he was offered the professorship of canon law in the university: but he thought proper to decline it. In 1180, he returned to his own country; and as great confusion prevailed at St. David's in consequence of the expulsion of the bishop, he was entrusted with the administration of that see for three or four years. In 1184, Henry II. appointed him his chaplain, and availed himself of his advice in the management of Welsh affairs. In the following year he was sent to Ireland with prince John as his privy-councillor and secretary; and was there offered the united bishoprics of Ferns and Leighlin, which he declined accepting, because he disapproved of the measures pursued by John. During his stay in that country, he was principally employed in collecting materials for two works relating to Irela

Ireland.
Ireland which he had projected. After his return to Wales, in 1187, he wrote and revised his “Topography of Ireland,” and at Oxford, he publicly recited the three parts of the work on three successive days, fasting on the first day all the poor of the city, on the second the principal doctors and scholars, and on the third scholars of inferior rank, fielders, and burgesses. In the following year he accompanied Baldwin of Canterbury on a journey through the mountainous parts of Wales, for the purpose of inculcating on the people the necessity of a crusade; and he was thus furnished with materials for his ‘Itinerary in Wales,’ which he afterwards published. At this time Girald took the crofs; but being otherwise employed at home, he obtained a dispensation from the pope’s legate for not pursing his voyage to the Holy Land in the retinue of king Richard I. Upon some difficulties, he retired from court in 1192; and took up his abode for six or seven years at Lincoln, where he pursued his theological studies and composed various writings. In 1196, he was solicited by the chapter of St. David’s, and the chief men of the country, to canvass for the vacant see; but in declining it, he made use of a saying which has become memorable; “Virum episcopalem peti, non petere, debere,” i.e. a man fit for a bishopric ought to be tried, and not fee. However, he soon changed his mind; and for being next year unanimously chosen by the chapter, he went over to Ireland to engage his relations in support of his claim. But during his absence, a mandate was issued from the archbishop and judiciary for the election of Geoffrey the prior of Llanthony. Girald appeared to the pope; and after much delay and three journies to Rome, he only so far prevailed as to annul the election, and to obtain the appointment of a new choice. Geoffrey was at length the successful candidate; upon which Girald resigned his arch-deanery of Brecon to his nephew, and withdrawing from public concerns, devoted himself to his studies. In 1215, he was offered the bishopric of St. David’s, but the offer was connected with conditions which he did not approve. The time of his death has not been precisely ascertained; but it is known that he was alive after the year 1222.

Giraldus Cambrensis was a voluminous writer; and there were few of the literary topics of his age that did not employ his pen. According to the account given of him by Mr. Thomas Wharton (Hist. of Poetry, diff. ii.), he was an historian, an antiquary, a topographer, a divine, a philospher, and a poet. Many of his works, he says, are written with some degree of elegance, and he abounds with quotations from the best Latin poets. But his style is in general pure, unaffected, concise, and full of quibles and conceits; nevertheless, many of these defects must be attributed to the times in which he lived. Whatever may be thought of the vanity which he manifests in speaking of himself, of his family, and of his performances, he was without doubt in a very great degree credulous, and to much addicted to fables, that his statement of facts is in many cases unworthy of confidence. With the events recited in his “History of the Conquest of Ireland,” he has intermixed all the propheties he could collect of Caleolus, Merlin, and various other impostors; and hence he was led to give to his history the title of “Vatican.” This work, and also his “Topographia Hiberniae,” have been charged by the Irish writers with numerous mistakes and falsities. They were first printed by Camden, at Frankfurt, in 1602. His “Itinerarium Cambriae” was printed with the annotations of David Powel. The purpoze of his “Ecclésiae Spectulum, five de monachis ordinibus, ex ecclesiasticis religionibus varis distinctionibus, lib. iv.” was to expose the vices of the monks, against whom he had conceived an inveterate hatred, so that he was accustomed to add to his itany, “From the malice of the monks, good Lord, deliver us.” Bog. Brit.

BARRY ISLAND, in Geography, the well-known of two islands off Cardiff point, on the coast of Wales, in the country of Glamorgan.

BARRY’S POINT, a projecting head land, on the west side of Little Island, up Cork harbour.

BARRY, in Heraldry, is when the shield is divided into equal parts horizontally, confiding of two colours: or that, Barry of six, argent and fable.

Barry Brandy Counterchanged, is when the bars are crossed by lines bendwise. See Plate of Partition lines.

Barry Indented, is when the lines which cross the field to form the bar are indented.

Barry Wavy and Barry Nebule, are formed in the same manner by the lines being wavy nebule.

Barry Longchique Counterchanged, is when the bars are crossed by lines bendwise, dexter and sinister. See Plate 3 above.

Barry Pile, is when the bars are charged with piles. See Plate 5 above.

BARRYERAS VERSSELLIAS, in Geography, is a large bay, with very good anchoring on the coast of Dalmatia, between St. John’s island and Syppomba island, 7 leagues north-east from it; situated in about 42° S. lat. and 6° W. of the mouth of the great river Amazon.

Barry, a town of Hungary, and chief place of a county of the same name, eight miles west of Leventz.

Bars, or Barco, Cape, lies on the east side of the passge into the White Sea, and to Archangel, from the N.W., and is the north point of the Gulf of Muren. N. lat. 66° 30’. E. long. 45° 45’.

BARSA, in Ancient Geography, an island near the coast of France, mentioned in the Itinerary of Antonine. See Isle of Bara.

BARSALUM, a town of Acre, situated on the banks of the Euphrates, on the coast of Samoter.

BARSALLACH POINT, in Geography, a cape of Scotland, on the coast of the county of Wigton, in Luce bay, 3 miles N.W. of Borrowhead.

BARSALLI, a kingdom of Africa, bordering on the river Gambia, and inhabited by a tribe of negroes called JALOFFS. The government of this kingdom is a despotic monarchy; and the people are in such an abject state of submission, that they fall on their faces whenever any one of the royal family appears. In time of war, every soldier has his share of booty; and the king contents himself with a very moderate portion. The kingdom is divided into a number of provinces over which the king appoints governors, called “bumeys,” who pay him an annual homage, and fend a certain tribute or revenue to the exchequer. These bumeys, though powerful and absolute within their respective jurisdiction, are subject to the absolute dominion of the sovereign. The king maintains his despotic power so completely, that he admits of no other counsellor besides his prime minister, who is himself in a degree the prime minister. This minister is also the general of the king’s forces, and the interpreter of his will, from the very letter of which he must never deviate. The king and court profess the Mahometan religion, though they pay little regard to that part of it which forbids the use of wine; for the king cannot live without brandy, nor is he ever more devout than when he is drunk. When he flands in need of a fresh supply of brandy, or of any other necessary, he sends to the governor of James fort, begging that he will dispatch a boat with the merchandise for which he has occasion; and for the payment he plundereth the neighbouring towns, and screws a certain
a certain number of his subjects, whom he sells for slaves, and exchanges for European commodities. The general dread of the people is a kind of calico furplice that hangs down below the knee, and is sometimes plaited about the waist; and they also wear a great number of gold tincture in their hair, ears, nose, and round their necks, arms and legs. The king of Barfalan, whose Moore saw in 1732, had a prodigious number of women; but when he went abroad, he was seldom attended by more than two, who seemed to be dressed out in the whole finery and jewels of the reign. The preface of his crown paid the same fervile homage to the sovereign with his lowest filthy: nevertheless it was usual for the king's children to dispute the right of succession with his brethren; and the longest sword generally gained the prize. Maj. Un. Hist. vol. 14 (164). See Jacobs.

BARSANIANI, in Church History, a sect who held all the errors of the Severians and Thedians.

BARSANITI, Francesco, in Biography, a native of Lucca, born about the year 1560, fitted the civil law in the universitas of Padua; but, after a short residence there, he chose music for his profession. With this view he placed himself under the tuition of fame of the ablest masters in Italy; and having attained a considerable knowledge both in the practice and theory of the art, he determined to settle in England, and came thither with Gemianali, who was also a Luccale, in the year 1713. He was a good performer on the hautbois when he first came over, and also on the flute: as a hautbois player, he found employment in the opera band; and derived considerable profit from teaching the flute. He published, with a dedication to the earl of Burlington, five folios for a flute with a thorough base, and afterwards six folios for the German flute and base. He also formed sonatas for two violins and a base, the first six folios of Gemianali. He continued many years a performer at the opera house. At length having encouragement to remove to Scotland, he went thither; and it may be said of him with greater truth than of David RVitzi, that he immortalized the muse of that country by collecting and making ballads to a great number of the most popular Scotch tunes.

About the year 1750, Bartani returned to London; but being advanced in years, he was glad to be again employed in the opera band as a performer on the tenor violin; and in the summer season, in that of Vauxhall. At this time he published twelve concertos for voices, and four after Sci Antiphone, in which he endeavoured to imitate Palestrina and the old ecclesiastical composers. But the profits arising from these publications were so small, that the fate did not cover the expense of printing them. Bartani was an excellent harmonist; but his productions were dry and fancif. He required small faults by correcting the productions of young composers, and making ballads to those of old pretenders to counterpoint. But towards the end of his life, he subsisted chiefly by the industry and economy of an excellent wife, whom he had married in Scotland, and the fladies and talents of a worthy and ingenious daughter, who, with the most promising voice and disposition for music, had been bound apprentice to a master who had undertaken to prepare her for a public finger, and with whom she had vanquished all the difficulties of the art to point of execution; but she totally lost her singing voice, on going to Oxford to perform at a choral meeting, by sickness in a flage coach; and never being able afterwards to sing, she was engaged by Colman as a comic actress at his theatre in the Haymarket; and having a great fund of natural humour, and a good figure, acquired great applause. The winter after she went to Ireland, and became a favourite actress in humorous parts, and at length was married to Mr. Daly, the manager of the Dublin theatre; but died soon after to the great regret of all who knew her.

BARSCHIERS, in Geography. See BARSCHIERS.

BARSCHLING, or BARTLING, in Ichthyology, one of the sphenus names of the common perch, Perca fluviatilis Vide Mrfighi, Daudb., &c.

Barse, an English name for the common perch, a well-known fresh water fish. It is also the name now in use for the same fish in the Saxon language, and is one of the many Saxon words we have yet retained.

BARSERS, in Geography, a town of Norway, 90 miles N.E. of Ronitsh.

BARSIR, a town of Persia, in the province of Kerman, 60 m. N.E of Sirjan.

BARSOUN, lies on the coast of Sweden, in the Baltic, leagues N. by W from the north end of Oland island, and nine leagues from the Wellersh mouth channel, among a labyrinth of rocks, impassable except by direction of pilots at Oland.

BART, a port on the southern coast of Nova Scotia.

Bart is also a township of Lancaster county, in the state of Pennsylvania.

BARTAPOUR, a town in India, in the country of Kerman, on an island in the Ganges, 93 miles east of Delhi, and 90 north of Lucknow.

BARTAS, William de Saluste du, in Biography, a French poet, was born, in 1544, at Montfort in Armagnac; and having entered into the service of Henry IV, he was employed by him in commissions to England, Denmark, and Scotland, in which last country James VI. would gladly have retained him. He was a Cavalier, and received in times of bad taste the reputation of a poet. His works were numerous, written in a style sometimes mean and barbarous, and sometimes timid and extravagant, and abounding with ludicrous and disgusting figures. His most famous work was "A Commentary on the Work of the Creation of the World," in seven books, which was held in high estimation, and passed through 30 editions, was translated into various languages, and formed a part of almost every religious library. Bartas is highly commended by Monf. de Thou for his candour, modesty, and simplicity of manners. Towards the close of his life he retired to his small estate of Du Bartas in Armagnac, and devoted himself to study. He celebrated in verse the victory of his master Henry, at Ivry in 1590, and died in the following year. His works were collected and published in folio, at Paris, in 1611. Gen. Dict. Nouv. Diet. Hist.

BARTAVELLE, in Ornithology, among the French naturalists, the same bird which Latham describes under the name of perdix rufus; which see.

BARTEN, in Geography, a town of Prussia, and capital of a small country called Barteland, in the province of Natagen, 40 miles S. E. of Königsberg.

BARTENSTEIN, a town of Prussia, in the province of Natagen, located on the river Alle. 28 miles south of Königsberg. This town was built in 1371, and at first called Ronithal.

BARTENSTEIN is also a town and castle of Germany, in the circle of Franzania and principality of Holenburg.

BARTERING, in Arithmetic and Commerce, the act of trucking or exchanging one commodity for another of like value.

The word comes from the Spanish baratar, to deceive or circumvent in bargaining; perhaps because those who deal this way usually endeavour to over-reach one another.

This is also called bartry, 13 Eliz. cap. 7.

In order to solve all questions that occur under this article, find the value of that commodity, the quantity of which
BARTHE, Nicholas Thomas, was the son of a merchant at Martigues, and born in that city in 1733. He was educated under the fathers of the oratory; and obtaining a prize from the academy of his native place, he afterwards became a member of it. His father had defined him for the bar; but his talents led him to the cultivation of polite literature and poetry. Removing to Paris, he devoted himself to the theatre; and in 1764, began to write for the stage. His pieces were "L'Amateur," "Fables Inédites," "La Mère jalouse," and "L'Homme perpétuel." The two first were well received, but the last did not possess sufficient energy and vivacity to please the public. Barthe then ceased to write for the stage, and engaged in a translation of Ovid's "Art of Love." He also published a collection of fugitive pieces in verse, in which species of composition he excelled. His epistles are also admired for their philosophical gaiety. Barthe blended with impetuosity of temper a friendly heart. Attached to social pleasures, he passed his time chiefly at Paris; and after having undergone the operation for an incarceration hernia, died in this city in 1795. Nouv. Dict. Histoire.

BARTHE, De Niephre (La) in Geography, a town of France, in the department of the higher Pyrénées, and chief place of an canton, in the district of Bagneres; 6 leagues south of Tarbes. The place contains 856, and the canton 10,426 inhabitants: the territory includes 180 kilometres and 22 communes. N. lat. 43° 4'. E. long. 0° 17'.

BARTHELEMY, John James, in Biography, a French abbé distinguished by his literary character, was born in Jan. 1716, at Caflis, a small port in Provence. At the age of twelve years he was sent to Marceilles, and pursued his studies in the college of the oratory under the instructions of father Ronaud. As he intended to devote himself to the ecclesiastical profession, he removed to the Jefuïtes' college for the study of theology and philosophy; but dissatisfied with his masters, he formed a plan of private study, which comprehended the Greek, Hebrew, Chaldee, and Syrian languages, and in the prosecution of which he brought on a dangerous illness. Upon his recovery he entered into the study, where he received the clerical tonsure; and by the influence of a young Maronite, he became a proficient in the Arabic language. From Mecejiles he retired to his family at Aubagne, and in this domestic retreat pursued his studies with unabated application. Among his friends at Marceilles, whom he occasionally visited, was M. Cary, who possessed a choice cabinet of medals and an appropriate library, to which he had access; and he was thus led to indulge the predilection for this kind of study, which distinguished his researches and character in the progress of his life. In 1744 he visited Paris, and was introduced by M. de Boze, keeper of the royal medals and secretary of the academy of inscriptions, to the most eminent members of the three academies, and also recommended to be his assistant in the care of the cabinet of medals. In 1747, he succeeded M. Buret as associate to the academy of inscriptions, M. Le Beau declining a competition; and when he was nominated by the minifter to the office of secretary to the academy, he waved the nomination in favour of M. Le Beau, as an acknowledgment of his liberality. In return, M. Le Beau, when he resigned this office, gave his interest to Barthélémy, who succeeded him. Thus did these distinguished rivals vie with each other in the exercise of a liberality which reflected equal honour on both. Barthélémy enriched the Memoirs of the academy by many communications relating to ancient monuments, and among others by a valuable dissertation on the inscriptions found at Palmyra by the English travelers. On the death of M. de Boze, in 1755, Barthélémy succeeded him as principal keeper of the medals. In the following year he followed M. de Stainville, afterwards duke de Choiseul and prime minister, to Rome, and made a tour to Naples, where the subterraneous treasures of Herculanum and Pompeii engaged his particular attention, and where he exerted himself with peculiar zeal in the preservation of the Greek manuscripts. As he was not allowed to make any tran
transcript, it was by some contrivance and with the help of a retentive memory that he was able to bring away a spiciemen of the most ancient mode of writing practiced by the Greeks. On his return to Rome he gained great applause for a new and ingenious explanation of the famous Mosaic at Palestrina, the ancient Præneste, which, according to him, related not to Syria, but to the emperor Adrian. In 1757, Barthélemy returned with his patron M. de Stainville to Paris, who, on his accession to the office of prime minister in 1758, anticipated and more than gratified his wishes, which were moderate, by various pensions, and at length by the place of secretary-general of the Swiss. When his patron Choiseul was banished, in 1771, to his seat of Chandos, in order to make way for D'Aguesseau, Barthélemy accompanied him in his exile, and as he determined to reign his secretaryship, an accommodation took place, by which he retained a pension of 10,000 livres on the poll. His income was now about 35,000 livres per annum, which he reduced, by several grants to indigent men of letters, to 25,000. This income he enjoyed with liberality; and he devoted a great part of it to the benefit of his family, and to the purchase of an ample and well-located library. Thus twenty years of his life were spent in literary affluence; but in advanced age he found himself reduced, by the forfeiture of places and pensions, to mere necessaries. During the last years of his life he was obliged to procure by putting with his library. This reverse of condition, however, he supported not without complaint, but even with gaiety. His celebrated work, "The Travels of the Younger Anacharsis," had been the labour and amusement of thirty years; its plan was laid in 1757, and it was published in 1788. It was received with universal applause, and in consequence of it he was admitted into the French academy by acclamation. Declining the office of king's librarian, which was offered to him in 1792, he continued to employ himself in the cabinet of medals, which had been augmented under his direction, so as to have doubled its number of ancient medals. It was his wish to have published a catalogue of its treasures, with faithful engravings, for the information of the learned throughout Europe; but though he had obtained, in 1757, the concurrence of the ministry, the embarrassment of the finances, and the critical events that disturbed the country, prevented the execution of this favourite project. In 1792, the infirmities of age crowded upon him; and the calamities of the times which a person of his age and character might have hoped to escape, aggravated his other complaints. Having been denounced under pretence of the crime of seditiocracy by a clerk belonging to the library whom he had never seen, he was arrested, and removed from the house of M. de Choiseul, on the 21 of September 1793, to the prison of the Ménalidonettes. With suchingular patience did he submit to this fate, that when he was conducted to the cell that had been prepared for him, he quietly replied. An order, however, was soon given for his liberation, and he was allowed out of cell, and carried back to the house of his kind and liberal patronesses. By way of repetition for this unmerited aggrievement, he was offered the place of chief librarian; but his increasing infirmities were a sufficient apology for declining it. His decay was gradual; but the severity of the winter of 1793 hastened the termination of his life, which happened on the 28th of April, on which day, two hours before his death, he was reading Horace, till the book fell from his cold hands. He then appeared to go to sleep, and in that state expired; having attained to the commencement of his 80th year. His corporeal frame is said to have been impregnated with an antique character; and his bust, sculptured by Houdon, and ex-

presive of the simple tranquility and conduct of a great mind, might suitably be placed between those of Plato and Aristotle. The principal work of this truly eminent person is his "Voyage de jeunes Anacharsis en Grèce," 3 vols. 4to. or 7 vols. 8vo., which details the history, manners, customs, literature, &c. of Greece, under the form of the supposed observations of a traveler Anacharsis, a disciple of the ancient Sceythian philosopher of this name. (See Anacharsis.) This person (see the author's advertisement prefixed to the work) is represented as visiting Greece in the year 573 B.C. and fixing his residence at Athens, whence he makes excursions, not only to the other Grecian cities, but to Egypt, Asia Minor, Persia, and the islands of the Aegean sea. On this basis of fiction is formed a real and instructive history, supported by the authority of the most approved ancient writers and by citations from their works. The narrative of Anacharsis is addressed to Aemines and Pheidon, a Persian satrap and his lady, whose characters are meant as portraits of the duke and duchess of Choisil. It is preceded by an introduction, in which is given a rapid but luminous view of the previous history of Greece. The elegance of style, the beauties of narration, and the judiciousness of reflection, render this the first work (says a biographer of approved judgment and taste) in point of entertainment and instruction, that so brilliant a subject has produced. It has added a capital piece to the literary cabinet of Europe, and its value has already been recognized by various editions, and translations into different languages. To the English edition in seven volumes, 8vo., is added an eighth in 4to. containing maps, plans, views, and coins, illustrative of the geography and antiquities of ancient Greece. An anonymous writer (see Monthly Review, Appendix to vol. lxxxi.) has suggested, that the learned author of Anacharsis may have taken the hint of his plan from the "Athenian Letters," consisting of the imaginary correspondence of a set of Greek gentlemen, the contemporaries of Socrates, Pericles, and Plato; but in reality the actual correspondence of a society of ingenious persons of the university of Cambridge, who, in this affirmed mode, communicated to each other the result of their researches into ancient history, and produced the best commentary on Thucydides that ever was written. However, the abbé Barthélemy having seen this in France, says the English translator, wrote a letter in consequence to M. Dutens, a respectable foreign gentleman residing in London, in which he affirms him that "it was not till after the publication of his work, that he heard of the Athenian letters; and that chance alone gave him the idea of it." A collection of miscellaneous pieces of the abbé Barthélemy, in 2 vols. 8vo., was published at Paris in 1798. Gen. Biol.

BARTHELEMY, St. in Geography, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Leufant, 24 leagues north of Toulouse.

BARTTHUS, GIUSEPPE, in Biography, a learned philosophical writer of the sixteenth century, was born at Chiarina, in Brandenburg, in 1575; and received his education at Gotha, and in several other academies both in Germany and Italy. His talents and attainments attracted notice at a very early period. At the age of 12 years he translated David's plaudits into verse, and in 1667 he printed a collection of all his Latin poems, written from his 13th to his 19th year. In his 16th year he composed a learned dissertation on the method of revising the Roman authors, and at 18 he wrote a commentary on the Æneis of Virgil. His acquaintance with the modern languages was extensive, and he made translations from the French and the Spanish. Such was
his attachment to literary studies, that he renounced every other employment and retired to Leipsic for the purpose of prosecuting them without interruption; and so numerous were his works, both printed and manuscript, that, according to the account of Mr. Bylde, few clerks in office have transcribed more papers than Bartholin. As to his morals they were not very correct, and like many other men of letters he engaged in several literary squabbles. Towards the close of his life, however, he devoted himself wholly to his religious duties: and it appears from his "Studia," published in 1614, that he was thus industriously employed. He died, after having been twice married, in 1658, at the age of 71 years. The chief of his works is his "De aerophylaxis," printed at Frankfort in 1624, fel comprehended in 26 books, and containing numerous emendations and illustrations of authors, both sacred and profane, to which he added two other such volumes left in MS.; his "Latin version of Æneas Gaza on the immortality of the soul," with an edition of the original joined to the work of Zachary of Mitylene," Leipf. 4to. 1653; "Notiz in Claudiano," 4to. Frankfort. 1653; "Comment. in Statio," 5 vols. 1664. As he trusted wholly to his memory, and never corrected what he had written, his works abound with mistakes and contradictions. Gen. Dict.

BARTHOULINE, Caspar, son of a respectable clergyman at Meltme in Sweden, a province of Sweden, and born the 12th of February, 1595, gave early signs of an uncommon capacity, which his father took care to cultivate, by giving him the best instruction his circumstances would permit in his own country. Being well grounded in the learned languages, he went, prompted by his thirst for knowledge, to Rudbeck, Wittenburg, and in succession, to the principal schools in Germany, France, and Italy. travelling generally on foot, his finance not permitting him to use the ordinary conveyances. Having accumulated a vast flock of learning, in languages and philosophy, but particularly in anatomy and medicine, to which his genius peculiarly inclined him, in 1610 he commenced doctor of physic at Basf; and the following year, going to Copenhagen, he was first made professor of the Latin language, and in 1613 of medicine, in the university there. This post he continued to fill until the year 1623, till the infidelity of a vow he had made, when afflicted with a febrile idea, that if he should recover he would dedicate a portion of his life to the study of divinity, he abandoned medicine for theology, to which he added himself for the remainder of his life; enjoying, with the professorship of theology, to which he was preferred at the university of Copenhagen, a canonry at Roschef. He died July 30, 1629, at Sora, a small town in the island of Zealand, leaving, as we learn from an inscription on his monument at Copenhagen, where he was buried, six sons and one daughter. His publications were numerous; and though not always well chosen as to the subjects, and adopting in them many popular and erroneous opinions since expounded, yet they were of considerable utility by exciting a spirit of inquiry; to which we may attribute more at least of the discoveries in anatomy, and other branches of natural history, made about that time. A complete catalogue of his works is given by Vander Linden, and by Haller, in his Bib. Anatomi, &c. The following will be sufficient to be noticed here. "Anatomica institutiones, corporis humani utrinque sexus historiam et declamationem exhibentes." Wittenburg, 1611, 8vo. This work, much improved and enlarged by his son Thomas, has passed through numerous editions. "Enchyridion phyicicum, ex praecl. et recentiss. philosophis accuratc c?ccinatnatur," Argent, 1625, 12mo. "Opulenta quatuor singularia. 1. De unico-
work, intitled "De Bibliothecae Incendio, Differtatio ad Titus," complaining heavily of the malignity of Vulcan. Among the numerous manuscripts destroyed by the fire, he laments in a particular manner those intended to elucidate his "Antiquitates puerperii variantium genitum, imprima Romanorun." "Opus (he says in his letter to his sons) vara eruditione, nii me fecellit opinio, referatum, cuius primi lineamenta duxi amnis abhinc triginta et amplius, in suo Ct. Walckii, qui id argumentum defiderari monuit. Meursius quidem, Graeci litterarum interpretes celebres, De Gracorum puerperio folia tria olim publici juris fecit, sed nula brevitate lectorum curiosum fatare non potest. Ad plura digniores ego, quique autorem veterum fetich affirmo, quique philologorum aliquorum observationes, quique variarum gentium inutilitatem, mortem Ritus, antiquitates uppeditatn, quique ad hoc argumentum illustrandum Ebrat doctores, Graeci sapientes, Romani scriptores conferre potuerunt, eum delictu felegi, et suo ordine reddidi, grata et diffusa varietate nascenti tempora percursi, quid nemo ante tautivitatem, quid in purpureo, quid poetae auctum fecerit. Ornatum librum juvare magnum, variis veteranis inscriptione, etfiguram passim Roxme, Neopoli, Caetce, Filotresina, in Scilicet magno studio a me collecta ex ruderibus, et doctorum virorurn monumentis, si induxas ex quio temporis, facia cognoscant, idem publico exsolvire poterimus. Jam in ipso puerperio fuctu, in partu labratis, extinctus, Lucianum itnicam nuncquam solicitast, nec prolum nec poltvertam. Ahit enim iniqua, unde negat risare quiescunt. His vetustate Calpurn, qui had his attention to the fame folior, and probably copied many of the notes made by his father, in some small degree required the accident by adding them with some observations of his own to a new edition of his father's works, which he published in 1676. On which occasion the father writes (see end of the work), "eripuit mihi Vulcanus argumentum bone de publico renedi, ut tibi occasionem proceret caligine proluns vetutatis obductam materiam propulsandi. Ex meo infortunio, tibi gloriosa victa vdtuiter. Quemadmodum Saturnus in cullo Paganorum cedere coactus est filio Jovi, et." The respect, however, that was every where paid him, and the letters of condolence he received from his numerous and learned correspondents, from to have from confided him, as these fearcours might have been any interruption in his labours, every year almost to the end of his life producing some new publication. The titles of a few of his dissertations, in addition to those already named, are here given; for the rest, the reader is referred to Vander Linden de Scriptis Medicis, but particularly to Haller's Libriph. Anatomiae, the Bib. Med. Pract. et Chirurg. in which ample tints of the titles of the works, of the different editions they passed through, and ayles of the contents of the most valuable of them, will be found. "Anatomica Anecrimitis difficiliter histiora," Panormi, 164.4.80."De Angina Puerorum Campaniae, Sicilique epidemica," Neapoli, 164.6.80. "De Luce Hominum et Brutorum," Latine, 1647, attempting to account for the emotion of light seen in trancers. In a later day he adds, "et de rariis et admirandis herbis, quae mociu lacuit." "Demus Anatomica Haffianis," containing a catalogue of the anatomical preparations, machines, &c. contained in his cabinet, 1642, 8vo. "Centuria qutsttor epilfularum medicarum," containing his correspondence with the most celebrated men of the age in which he lived. This valuable collection has been completed, and republished at the Hague in 1749, in five volumes, 8vo. "De infolitis partibus humani vis." Haffii, 1646, 8vo. "A collection of histories of states voided by the navel, anus, et per os etiam, si dies placet." Historiae Anatomiae, Cent. vii. Two centuries, forming two small volumes, were published at a time. Though some of the observations, taken on the credit of other observers, are apocryphal, and should not have been admitted, the number of authentic and curious articles contained in these volumes have flamed a value on them which time is not likely to obliterate. The last work we shall mention is the "Acta Medica et Philosophica Haffi- nica," of which four volumes in 4to, were published by him, the fifth and last volume by his son. He began making this collection, which contains many of his own productions but a much larger proportion from correspondents, soon after his return to Copenhagen, driven there by the destruction of his library. As in all similar collections, amidst some very valuable articles many insignificant and useless pieces will be here found. He died in 1685, leaving five sons and three daughters. Two of the former, Caspar and Thomas, continued in the steps of their father, "at hau hofibus suis," contributed to the collection last named, and left other anatomical and medical works. Of the others we have no account. Haller, Bib. Asiat. et Bib. Med. Pract. Elnot. Hist.

BARTHOLINE, ERASMUS, a younger brother of Thomas, born at Rothchild, August 13, 1625. Following the steps of his father and brother, he travelled through England, France, Germany, and the Low Countries; and having acquired much valuable knowledge in natural philosophy and medicine, went to Leyden to perfect himself in those studies, where he continued three years. In 1654 he went to Padua, where he received the degree of doctor in medicine. On his return to Copenhagen, he was appointed professor in mathematics, and was rewarded with a seat in the grand council of Denmark. These honourable offices he continued to fill with great credit to the time of his death, Nov. 5 1698. In the Acta Haff. vol. iv. he gives an account of a quartan fever, epidemic in Copenhagen in the year 1679, which he cured in himself, as well as in many others, by giving a single draught of the Peruvian bark on the accbission of the fever. In 1661, he published "De Figura Nivis Differtatio," with the observations of his brother Thomas on the use of snow in medicine; in 1664, "De Comitis," 4to. Haff. in 1674. "De Natura Mirabilibus," also 4to; and in 1679, "De Acce Hafffenis," Frank. 8vo. Albert, another of the sons of Caspar Bartholine, left behind him a small work "De Scriptis Dauerorn," which was published by Thomas at Copenhagen, 1666. 4to.

BARTHOLINE, CASPAR, eldest son of Thomas, was born at Copenhagen in 1650; and treading in the steps of his father and grandfather, acquired almost equal reputation with them. Though accused of plagiarism, and of affuming to himself the honour of discoveries made by others, yet the merit of polishing genius and industry cannot be denied him. Indeed Haller, who had spoken lightly of him at first, on the authority of Swammerdam and Drenckent, treated him some years after (Bib. Med. Pract. v. 3: p. 34.) with more respect, calling him, "Vir acuti ingenii, qui demum ad magnos honores, et locum honoratum in regio insigni erudit." The early part of his life was spent in travel, in which he engaged in the acquisition of knowledge; and he had the happiness of associating with Roych, Swammerdam, Daveney, and other celebrated anatomists, all eagerly engaged in the same pursuit. Being at Rome on his travels, at the age of 22 he published, in Latin, a learned and accurate treatise on the flutes, or rather on the wind-instruments in general, of the ancients, under the title, "De Tuba Vetricum, et engine antiquo uius, libri tres." This work first appeared at Rome in 1677, dedicated to cardinal Sigismund Chigi. The second and bolt edition was published at Amsterdam, 1679, 12mo. with double the number of copper-plates with which the Roman edition had been ornamented.
representing ancient musical instruments from drawings chiefly made from ancient sculpture, which are well executed; and illustrated with quotations from the classics where their life is mentioned. No book of the kind seems to have been written since of equal authority; as recourse has chiefly been had to this little tract, by Bianchini, Bonanni, and others who have written expressly on the subject of ancient musical instruments. In 1678, he was received doctor in medicine at Paris. Returning thence to Copenhagen, he was made professor in medicine at the university there, and was in such high estimation as to be raised by the king, in the latter part of his life, to considerable offices in the state. Besides republishing several of the works of his father, and contributing largely to the Acta Haffiensia, his own disquieted treatises are sufficiently numerous and valuable to entitle him to rank with the celebrated authors of that age. The titles of a few of them follow; the remainder will be found in the Bib. Anat. et Med. Prac. of Haller. "Exercitationes medicinae varius generis, imprimit Ansonian," Leid. 1675, 8vo.

In the seventh, he gives an account of a ptychus efficacious in stopping hemorrhages, taken inwardly. An experiment was tried with it successfully before the king. "De Diaphragmati structura nova," Paris. 1676, 8vo. Drelincourt claims the honour of this discovery, and as Caspar B. was only twenty-two years of age when he published this account, Haller seems to decide in favour of the claim of Drelincourt. "De Formatione et Nutritione Fetus in Utero," Haffine, 1678, 4to. "Specimen Historiae Anatomiae Partium Corporis Humani," Haffine, 1701, 4to. He died early in the last century, but in what year is not known. His brother Thomas was appointed to the professorship of law and history. One work of merit is attributed to him, "De Catus Mortis a Dania gentibus contempto," and a dissertation published in the fifth volume of the Acta Haffiensia, "De Vermibus Aceti, et de Vermiculis feninalibus." The rest of the family of Thomas, are said to have distinguished themselves so as to be appointed to honourable situations; but these perhaps were rather the homage paid to the virtues and talents of their ancestors than to their own merit, as none of their works have been noticed by bibliographers. Vander Linden. Haller. Bib. Anat. et Med. Prac.

**BARTHOLOMEUS DE CLANVILLE,** an English writer who flourished about the middle of the 15th century, wrote "De proprietatibus rerum," which was first printed in fol. by Caxton, 1480, translated into English by Trevisia, and printed by Wynken de Worde in 1507, and again by Bertholst fol. 1533. The original has passed through many editions. In the seventh chapter, he treats of many diversities of ad carne; taken, Friend X's, principally from Conflantine. Haller. Bib. Med. Prac.

**BARTHOLOMEUS.** St. in *Geography,* a town of Germany, in the circle of Bavaria and provostship of Butchcfeldgen, near the Kongig, 15 miles south of Reichenhall.

**BARTHOLOMEO DE XONCIANI,** St. a town in North America, in the province of New Mexico.

**BARTHOLOMEO.** A town of North America, in Mexico, and province of Guispe, chiefly populated with Indians,—Alfo, a town of Italy, in the kingdom of Naples, and province of Otria 13, 11 miles I.S.E. of Nard. —Alfo, a town of Italy, in the kingdom of Naples, and province of Constantza, 6 miles south of Volturnara.

**BARTHOLOMEW.** St. in *Geography,* one of the 12 apostles, whose native country was Galilee, is supposed by some writers to have been the same with Nathanael, one of our Lord's first disciples. It has been generally thought, that he preached the gospel in India; and that he carried thither the gospel of St. Matthew in Hebrew, where Panteaus found it towards the close of the second century on occasion of his peripatetic into that country for the same benevolent and laudable purpose. St. Jerome adds, that Panteaus brought this gospel home with him to Alexandria; but this fact is disputed; and St. Jerome is supposed to have mistaken the words of Eusebius, who only says that the Christians of Lyra had preserved that Hebrew gospel till the time of Panteaus. (See Euth. H. E. lib. v. c. 10. Hieron. de Vr. Libr. c. 36.) It has been alledged, that Bartholomew preached in Arabia Felix and Persia; and that, returning by way of the more northern and western parts of Asia, he preached at Hierapolis and in Lycaonia; and that he died at Albania, probably at a city among the Albanians, on the Capuan sea and confines of Armenia. At this latter place it is said, that he was slain alive by Advagius, brother to Polemon, king of Armenia. From hatred to the Christian religion, which the apostle had induced Polemon to embrace. But the time, place, and manner of his death have not been satisfactorily ascertained. Dionysius the Areopagite cites the writings of Bartholomew; and Jerome (ubi supr., et Pr. in Comment. in Matth.) mentions a "gospel of St. Bartholomew," which pope Gelasius, in his decree, refers to the clafs of apocryphal books. Of this book there are not any fragments extant; unless, as Mr. Jones (Method of setting the Canon, &c. vol. i. p. 211.) inclined to think, it was the same with the gospel of St. Matthew, which was used by the Hebrews or Nazarenes. This learned writer infers from the relations of Eusebius and Jerome, that this gospel was that which had been found in India; but that it had undergone many interpolations and additions: for, says he, it cannot be thought improbable that those who heard St. Bartholomew preach and explain this gospel to them should after his departure rather call it by his name, whom they knew, than the name of Matthew, whom they did not know. Blandines Charriales aubres (Hist. Ecc. l. iv. c. 32.), that Bartholomew dictated the gospel of St. Matthew to them from his memory, and did not bring it along with him.

**BARTHOLOMOW, of the Martyrs,** a Dominican monk, and archbishop of Braga, was born at Lisbon in 1514, and entered into the Dominican order at the age of 14; on which occasion he renounced his family name of Fernandez, and assumed that of the church in which he had been baptized. Having taught theology for 20 years, at great length, with great readiness and the charge of the archbishopric of Braga, to which he was appointed by Queen Catherine. Soon after his appointment, he was deputed, in 1561, to attend the council of Trent, in which he strongly insisted on commencing all reforms with that of the clergy. On his return from the council, he devoted his whole time and revenue to the exercise of benevolence. Accordingly, he used to say, "I am first physician to 1400 hospitales, which are the phials of my doocede." During the famine which afflicted Portugal in 1567, and lasted seven years, the poor of Braga were liberally supplied by the archbishop; and he even extended his donations to those of superior condition who felt the severity of the times. The famine was succeeded by a plague, and on this occasion the archbishop, who resided at Braga and obliged the parochial priests to do likewise, contributed in so small degree to the relief and comfort of the distressed. Having, after repeated solicitations for the poor, obtained leave to resign his archbishopric, he retired to a monastery of his order at Viana, where he spent the last eight years of his life in study and religious exercises; and here he died in 1592. In 1733 he was beatified by Clement XIV. The writings which he left were collected and published at Rome in 2 vols. folio. 1744. Nouv. Dict. Hist.
Bartholomew’s Day, St. in the Calendar, a festival of the Christian church, celebrated on the 24th of August.

On this day, in the year 1662, the act of uniformity which obtained the royal assent on the 19th of May, took place; in consequence of which about 2000 ministers relinquished their preferments in the church, or refused to accept of any upon the terms of this act. See Uniformity.

It was also on the eve of St. Bartholomew in the year 1572, that orders were issued for extending the horned fishery which had been begun at Paris, in consequence of which the town of Paris, as this fishery was liked in allusion to the Sicilian vespers, were repeated in Marseilles, Troyes, Angiers, Touloufe, Rouen, and Lyons: so that in the space of two months, 30,000 Porpoises were butchered in cold blood; if that expression may be used, in speaking of people influenced by the most detestable passions.

Bartholomew’s Hospital. See Hospital.

Bartholomew, St. in Geography, one of the Caribbean islands in the West Indies, about 27 miles north of St. Christopher’s and in circumference about 24 miles. It was peopled in 1638 by Poincy, the French governor of St. Christopher’s, and enjoyed by the French without molestation till the year 1689, when a defance was made upon it by Sir Timothy Thornhill, who ravaged the country, and carried off about 750 of its inhabitants, with their cattle and effects. The English government, however, disapproved of this conduct, and allowed the inhabitants to repopulate their island, as subjects of Great Britain. At the peace of Ryswick, it was restored to France; but as long as it continued in their possession, it was a nest of privateers, and it has had fifty English prizes in its harbour at the same time. It was ceded by France, in 1783, to the Swedes. The shores of this island are dangerous, and cannot be approached without a good pilot. The only port in the island is “Le Carénage,” near which stands “Guattiva,” the seaport town in the colony. This port is situated on the western side, and has excellent moorings; but it cannot admit vessels that draw more than nine feet of water. However, it will contain 100 such vessels; in which respect it is superior both to St. Eustatia and St. Christopher’s. The bay of “Colombier” is deep enough for large ships; but it has no town on its banks; nor has “Le Carénage,” any town belonging to it, but it is one of the several ports of trade. Its soil is but indifferent, and only a small part of it admits of cultivation; and yet it produces tobacco, cotton, and cassava, and abounds with woods of various sorts. The plantations that most abound are those of cotton, which succeed very well. The practice of the planters is to sow four or five grains of the seed in a hole, and when the plants appear they pluck up all but the strongest. After the first crop, they cut down the branches, and the plant pushes out new shoots, which bear like the original item; but after the second crop, the seeds must be again sown. The fences of these plantations are aloe trees, which are placed in a straight line, and as close together as possible; and when they arrive at maturity, they are impenetrable either by men or animals. St. Bartholomew also furnishes the neighboring islands with a peculiar kind of lime; and its birds are very numerous. The climate is in general healthy; though at certain times of the year the weather is variable. For nine months in the year it is pleasant; for, though the heat is scorching, the air is cooled and purified by a breeze, which is very refreshing. Hurricanes prevail from the middle of July till the middle of October. The population of this island is much increased since it has belonged to Sweden. At Guavina are Swedes, English, French, Danes, Americans, and Jews: but the planters are chiefly French. The natives generally live, without being subject to much ill health, to an old age. The men are robust, but the women are light, feeble, and indolent; and are customarily attended by slaves, who are employed in keeping off the infestations that would incommodate them. The houses are made of wood; and some of them are raised upon stone pillars, so that the wind can pass under them. Their windows are mere openings in the sides, with window-shutters or lattices. The inhabitants are supplied with fresh provisions, flour, dried fish, and salted meat from the continent of America. Although the island abounds with mountains, it is deficient not only of lakes and rivers, but even of springs. The fresh water is supplied merely by the rain, and is kept in cisterns; and it is sometimes produced from St. Christopher’s, and often at the charge of twelve lives per ton. The chief products for exportation are sugar, cotton, linum vitae, and iron wood. The coins used in this island are the moidore and the piastre; and they have also a licentious money called the pifon, a worth something more than 2/3 of a piastre; and a small silver coin called a dogg, and another coin called a bitt, of the value of 6 drachms. See “A Voyage to the Islands of St. Martin, St. Eustatia, and St. Christopher,” undertaken at the expense of the Academy of Sciences at Stockholm.” N. lat. 17° 50'. W. long. 6° 11'.

Bartholomew, St. an island in the Southern Pacific ocean, being one of the cluster of islands, called the New Hebrides. N. lat. 15° 4'. E. long. 157° 17'.

Bartholomew’s Islands. lies in the straits of Magellan, half a league E.N.E. from Elizabeth island. S. lat. 52° 50'. W. long. 71° 14'.

Bartholomew’s Island, or Whermyesen, is situated on or near the coast of New Guinea. S. lat. 8° 15'. E. long. 138° 35'.

Bartholomew, St. a parish in Charlestown diocese, in South Carolina, which, by the census of 1790, contained 12,606 inhabitants, of whom 10,538 were blacks. It sends three representatives and one senator to the state legislature.

Bartholomew, Cape, St. is the southernmost point of Staten land, in the straits of Le Maec, at the south end of South America. To the W.N.W lies Middle Cape, and between them is a bay. To the easterly of it is a small island.

Bartholomew, is the name of a ledge of rocks, nearly west from the S.W. extremity of St. Mary’s island, the largest of the Brittle islands; between which and St. Mary’s island, is a channel called St. Mary’s sound.

BARTHOLOMITES, in Ecclesiastical History, a religious order founded at Genoa in 1307; but on account of the irregular lives of the monks, the order was suppressed by pope Innocent X. in 1650, and their effects were confiscated. In the church of the monastery of this order at Genoa is preferred the image which, it is pretended, Christ sent to Abgarus.

Bartisch, George, in Biography, surgeon and oculist at Drefden, born at Königsberg about the middle of the 18th century, is said to have invented a speculum to fix the eyelids while performing an operation on that organ; which was improved by Verduyn, and still further by Rysch and Kau, for they contended for the honour attached to it. He wrote a treatise on the diseases of the eyes, in the German language, published at Dresden in fol. 1753. It has since been translated into Latin, and passed through several editions. There are many plates; those representing the different parts of the eye are taken from Vefalus. Infected with the sepsis of the age in which he lived, he attributes some of the disorders of the eye to witchcraft.

BARTLETT, a plantation of America, in Hillsborough county, New Hampshire, containing 248 inhabitants.

BARTMEISE, in Ornithology, the name of the bearded titmouse, parus hirundo in Frich. Hist. Birds.

BARTOLET, in Biography. See FLAMEL.

BARTOLI, Daniel, a learned Jew, born at Ferrara in 1608; a author of many profound and useful works, written in Italian with a precision and purity of style which have inclined his countrymen to rank him among the first scientific writers in their language. The great historical work of Bartoli appeared in 4 vols. folio, printed at Rome in succession from 1670 to 1673. After the life of St. Ignatius, he begins with the establishments and labours of the Society in Asia, comprised in 3 vols. and divided into those of the East Indies, Japan, and China. In two other volumes he treats of England and Italy. This performance was translated from the Italian into Latin by Father Giannini, and printed at Lyons. He published at Bologna, in 1680, a work in 4to, intitled “Dil fuoiu de remori armoric e dell’ otro” (of harmonic vibrations of found and of the ear). In this truly scientific and ingenious work are to be found several discoveries in that art, which were perused by polished writers on the subject. It contains four dissertations; the first treats of the similarity between the circular undulations occasioned in still waters, and the propagation and motion of sound. The second, of the motion of sound compared with that of light: of echoes, or reflection of sound, and of its augmentation in a whispering room or gallery. Third, of harmonic vibrations and ratios of sound; of sym pathetic sounds; of the breaking a glass with the voice. Fourth, of the mixture of sounds: of confluence; harmonics; and the immense increase of sounds in a vessel, or inclosed place, by repercussion. With many other curious enquiries; and ends with the anatomy of the ear.

BARTOLI, Pietro Sante, called Perugino, an engraver of reputation, was born at Perugia about the year 1675, and reduced chiefly to Rome, where he died in 1700. He is mentioned as a painter, but his character as an engraver is more established. He drew in a correct, agreeable style; and his plates, which are chiefly etched, are executed in a free, masterly manner. His distinguishing excellence consisted in copying the bas-reliefs, and other works of the ancients. His manner is original; and though his name is not always marked at full length upon his plates, they are easily distinguished by persons acquainted with his works, as the freedom and lightness of his pencil cannot easily be counterfeit. Among his detached prints are: “St. Charles kneeling, accompanied by an Angel,” from Antonio Caracci; and the “Adoration of the Shepherds,” from Annibale Caracci. Simut.

BARTOLO, a lawyer of the 14th century, was born in 1343 at Saliscirato, the ancient Sentinum, in the march of Ancona, pursued the study of the law at Perugia and Bologna, and attained to such eminence, that he was distinguished by the pompos titles of “Light and Star of Jurisconsults,” “Master of Truth,” “Lamp of Rights,” “Guide of the Blind,” &c. In 1339, he was elected professor of laws at Pisa; and after remaining 11 years in the exercise of this office, he removed to Perugia, where he opened a school of law, celebrated through Italy, and frequented by a great number of students. When Charles IV. visited Perugia, in 1355, Bartolo secured his favour to such a degree, that he obtained for Perugia all the privileges usually granted to universities, and for himself the titles of counsellor, and domestic commissar of the emperor, with permission to bear the family arms of the king of Bohemia. Bartolo is said to have acquired great wealth, and to have died at Perugia in the year 1359; but the time of his death is not precisely ascertained. He was of a feeble constitution, and his temperance was such that he is said to have weighed his food. His learning and researches were extended beyond his own profession, and his regard for the scriptures induced him to make the Hebrew language the object of his particular attention. His works, comprehended in 10 vols. folio, were printed at Lyons in 1545. Nouv. Dict. Hist.

BARTOLOCCI, Julius, a Cistercian monk, was born at Cellano in Abruzzo, in the year 1613, and became famous for Hebrew and Rabbinical learning. Having been 36 years professor of Hebrew in the college of Neophytes at Rome, and also Hebrew writer in the Vatican, he died in 1687. His great work is intitled “Bibliotheca Magna Rabbinica de Scripturis et Scriptis Hebraicos,” 4 vols. folio. It was printed by the college “Propaganda,” and the volumes appeared successively in 1675, 1678, 1683, and 1693. The fourth volume was completed by his scholar Iambonati, who, in 1694, added a fifth intitled “Bibliotheca Latino-Hebraica.” This work furnishes valuable materials for guiding the interpreters of the Hebrew scriptures. Bartocci left also annotations on the book of Tobit. Moreri, BartoLOIO, Baccio. See BACCOLO, BRENNER, See FREIBERG.

BARTON, Elizabeth, called commonly “The Maid of Kent,” was an enthusiastic imposter, first known in 1525, as a servant at Aldington in Kent. Being subject to hysterical fits, which were attended with a variety of Vanities and dilutions, the superlubions of the age led the common people to believe that she was supernaturally inspired. Matters, the parson of the parish, thought that she was a fit person to be employed in order to support the declining cause of Rome, or to give celebrity to his own chapel, and accordingly resolved to exhibit her as a prophetess. With this view, he and some of his friends took her under their tuition; and taught her to act her part to well, that she not only deluded the common people, but imposed on the credulity of several persons of rank and learning; among whom were Sir Thomas More, Fisher, bishop of Rochester, and Warham, archbishop of Canterbury. The monk and ecclesiastics, who were appointed by the latter to investigate this business, made a favourable report, and encouraged the imposture. The nun, for such was the character she had now assumed, was conducted in triumphal procession, and attended by a mob, to the chapel of the Virgin at “Court of Street;” and when she appeared before the image of our lady, she fell prostrate in one of her trances, delivering rhymes, speeches, &c. all of which tended to the honour of that faint, and of the Papist religion. Having for some time performed in this way, very much to the honour and profit of her employers, she was further instructed to denounce menaces against the king on account of his divorce from queen Catharine, and his marriage with Anne Boleyn, and also his enmity to the church, and to declare his subjects absolved from their allegiance. Henry, who had for some time despised the imposture and its abettors, being at last justly incensed, inflicted an order that, in November 1533, the maid and her accomlices should be apprehended, and brought into the star-chamber; all of whom, upon their examination, confessed the imposture, and afterwards publicly confirmed their confession before the people at St. Paul’s church. Some attempts having been made to induce the nun to retract her confession, measures of severity were adopted, and an act of parliament was passed (25 Hen. VIII. c. 12.) which attained them of high treason, for a conspiracy against the crown and life of the king. Accordingly Elizabeth Barton, and five of her accomplices, were beheaded at Tyburn.
B A R

born in April 1534; the deluded man, who was a simple and ignorant woman, having made a previous acknowledgement of her crime and the justice of her sentence. Dug. Brit.

Barton-upon-Humber, in Geography, a large market-town in Yorkarborough hundred, Lincolnshire, England, 34 miles from Lincoln, and 167 north from London. It consists of several streets irregularly built, and has two large churches. By an ancient register this appears to have been a much more considerable and extensive place than at present; but the destructive plague which infested it in the reign of Queen Elizabeth, may, in a great measure, have caused its decline. The moat early pasture to Hale is from Barton-Nevy. The market is held on Monday; and it has a fair for horse, oxen, and sheep.

At Horknow, in this neighbourhood, was lately discovered a curious Roman telferated pavement, which is particularly described by Mr. Lysons, in the first part of "Reliquiae Romanae." This town includes 412 houses, inhabited by 1709 persons. N. lat. 53° 40'. W. long. 0° 22'.

Barton, a township of Orleans county, in the state of Vermont, America, formerly in that of Orange, lies S.W. of Brownington; 6 miles S.W. by W. from Willoughby lake, and 140 N. easterly from Bennington.

Barton, in Devonshire, and the west of England, is used for the demesne lands of a manor. Also for the manor-house. And, in some places, for out-houses, fold-yards, &c.

BARTRACH. In Geography, an island in the bay of Killala, at the mouth of the river Moy, about 2 miles long, and half a mile broad; 2 miles N.E. of Killala.

BARTRAMIA. In Botany. See TRAUFFETTA.

BARTSA. In Geography, a town of Hungary, 14 miles N.N.E. of Széchen.

BARTSENLU, a town of Arafic Turkey, in the province of Natalia, 32 miles S. of Kutsia.

BARTSIA, in Botany, a genus of plants so named by Linnaeus, in memory of his friend Dr. Bartch. It is an intermediate genus between rhinanthus, euphrasia, melampyrum, and pedicularis; distinguished by its coloured calyx. Lin. gen. 730. Schreb. 1796. Juss. 300. Clus. didyma angustifolium. Gen. Char. Cal. perianth one-leaved, tubular, permanent; mouth oblong, two-lobed; lobes emarginate, coloured at the top. Cor. monochlamys, tinged; upper lip crept, fladder, entire, longed; lower, reflex, trident, obtuse, were small; filaments were small, bristle-shaped; the lower of the upper lip; two somewhat shorter. Stem. Anther two. Thers. oblong, approximating under the top of the upper lip. Pila. Germ ovate. Style, filiform, longer than the calyx. Stigma, obtuse, nodding. Per. capulose ovate, compresse, acuminate, two-celled, oblong, two-valved; partition contrary to the valves. Seeds. Numerous, angular, small.

Eff. Gen. Char. Cal. two-lobed, emarginate, coloured. Cor. coloured less than the calyx; upper lip longer.

BARUCH, in Scripture Biography, was the son of Neriah, of the tribe of Judah, and the faithful disciple and servant of the prophet Jeremiah, who employed him as his secretary or amanuensis. This prophet having received orders in the reign of Jehoiachin king of Judah, whilst he was in prison, to write all his prophecies till that time, dictated them to Baruch, by whom they were read to the people assembled in the temple on occasion of the feast of expiation. B. C. 605. Baruch terrified by the threats contained in the roll which he had read to the people, was encouraged by an assurance that, notwithstanding all the calamities which would befall Judah and Jerusalem, he should obtain a deliverance. (Jer. xli.) Archbishop Usher and Dr. Prideaux are of opinion, that this roll was read a second time to the people, in the fifth year of Jehoiachin, B. C. 603, after which it was committed to the flames by the king himself; and the Jews keep an annual fast, even to this day, in commemoration of the burning of the roll; the day marked for it in their calendar is the 29th of Calue, the sixth month of the Jewish year, and corresponding to our November. After the burning of this roll another was immediately written, by God's special command, from the mouth of the prophet by the hand of Baruch; and to this were added many other words, and particularly that prophecy with respect to Jehoiachin and his house, which is denounced against them for this impious fact, in the 30th and 31st verses of the 52d chapter of Jeremiah. In the fourth year of Zedekiah (B. C. 594.), Baruch went to Babylon with his brother Neriah, and carried thither a written account of the prophecies contained in the 52d and 53d chapters of Jeremiah, which denounced the judgments that were to be executed upon Chaldea and Babylon by the Medes and Persians. Baruch, having read these prophecies to Jehoiachin and the other captives, threw the roll that contained them into the Euphrates, as the prophet had commanded him. Baruch accompanied Jeremiah into Egypt, and after the death of the prophet, he retired to Babylon, where, according to the rabbins, he died in the 12th year of the captivity. The book of Baruch, contained in the Apocrypha, is an epistle, or letters, to the captivity, by King Jehoiachin and the Jews in captivity with him at Babylon, to their brethren that were still left in Judah and Jerusalem, with an historical preface, in which it is related, that Baruch being then at Babylon, drew up this epistle in the name of the king and the people, by their appointment, and read it to them for their approbation; and that a collection having been made, the epistle with the money was sent to Jerusalem. No Hebrew copy of this book is extant; but there are three copies, one in Greek and the other two in Syriac. The Jews have not received this book into their canon; nor is it found in the ancient catalogues of the scriptures, cited by the fathers and the councils. In the latter catalogues, it is annexed to the book of Jeremiah, and cited by some of the fathers as a part of Jeremiah. St. Jerome (Præf. in Jerem.) expressly rejects it out of the canon; nor does he translate it, because it was not in Hebrew, nor received by the Hebrews. On the other hand, St. Cyril of Jerusalem, and the Latine councils held by A. D. 356, mention Baruch among the canonical books of Scripture. In both the catalogues which they have given, these words occur: "Jeremias cum Baruch Lamentationibus et Epistolam." But it has been alleged, that by these words they meant to express no more than Jeremiah's prophecies and lamentations; that by the epistle, is meant merely the epistle in the 29th chapter of Jeremiah; and that the name of Baruch is added only because he had collected these together, and annexed the last chapter, which is supposed to be Baruch's, the prophecies of Jeremiah, ending with the 51st chapter, as it is positively said in the last words of it: and it must be acknowledged, says Dr. Prideaux, that as neither in St. Cyril, nor in the Latine council, any of the other apocryphal books are named, it is very unlikely that by the name of Baruch, in either of them should be meant the apocryphal book under this title, which has the least pretence of any of them to be canonical. Although the church of Rome has admitted it, and its authority has been sanctioned, after some hesitancy and difficulty, by the canon of the council of Trent, it is condemned by Protetants to the class of apocryphal books. Prof. Conn. p. 1. b. i. vol. i. p. 87, &c. Depuy's Eccl. Hist. vol. i. p. 26.

BARUCO, or BARICA, CARM. in Geography, is the western point of Golfo Dulec, or fresh-water bay, and distant from it about four leagues, on the S.W. side of the islands of Parma, in the Northern Pacific ocean, S. E. S. from Cape Nelson, and S. E. from the gulf of Salimas. N. lat. 8° 26'.

BARUD, the name of several small places of Egypt, on the east and west side of the Nile, situated not far from Manfouret, Front. and Dendera.

BARVER, a town of Germany, in the circle of Weilphala, and county of Dicpholz, six miles E. N. E. of Diepholz.

BARVILISKI, a town of Lithuania, in the palatinate of Troki. 12 miles S. W. of Troki.

BARULES, in Church History, a feast which maintained that the Son of God had only a phantom of a body; that souls were created before the world, and that they lived all at one time.

BARUM, in Geography, a town of Germany, in the circle of Lower Saxony, and principality of Luneburg; 10 miles south of Luneburg.

BARUST, in Commerce, an Indian measure containing 17 gantans; it ought to weigh about three pounds and a half avoirdupois.

BARUTH, in Geography, See Bariout, and Berystus.

BARUTH, a town of Germany, in the circle of Upper Saxony, 22 miles S. E. of Potsdam, and 34 N. E. of Wittenberg.

BARWICK, PETER, in Biography, of a respectable family of Witheraback in Weilmorland, was at a proper age admitted of St. John's college in Cambridge. Where, in 1642, he took his degree of Bachelor in Arts. Quitting that seminary during the troubles which at that time disturbed the country, he was entertained at the house of Mr. Sacheverel of Leicestheret, as tutor to his son. In 1655, he took his degree of Doctor in Medicine, and soon after was made physician in ordinary to king Charles II. which occasioned him to come to London, where he soon acquired considerable reputation for his skill in his profession. He is said to have excelled particularly in his treatment of the small-pox, as well as of typhus and malignant fevers; perhaps following the method recommended by Sydenham in those complaints: but he has left no publications on these subjects. He wrote very ably in defence of Harvey's doctrine of the circulation, at that time much agitated; and M. Carrera attributes to him a treatise, published in London, 1671, 4to. "De in qua Medicinae Annum Exspectat." But the work by which he is principally known, is the life of his brother John Barwick, late dean of St. Paul's, written in elegant Latin. It was published in 1721, 4to, large 8vo, by Hilkiah Belford, and an elegant portrait of the doctor, engraved by Vertue, affixed to it. His defence of the "Eikon Basilike," against Dr. Walker, which was written in the 74th year of his age, "does not only flow, but..." Grange...
Granger says, "the warmth of his loyalty, but discovers not a little of the perversity of old age." He died August 1705, in the 85th year of his age, highly honoured and respected by all who knew him. Granger's Biog. Hist. of England. Ely, Dict. Hist.

BAR

Barwick, John, an eminent English divine of the 17th century, and dean of St. Paul's, was born at Wethersfield, a little village of Welford, in 1612; and being designed for the church, he was sent to school at Sedbergh in Yorkshire, where he manifested early indications of genius and pertness. In 1631, he was admitted into St. John's college in the university of Cambridge, where he became so distinguished, that he was chosen, at the age of twenty, to manage a dispute relating to the election of a master, which was heard before the privy council; and by his conduct in this business, he acquired celebrity in the university, and was also taken notice of at court, and by the ministry. Having taken several degrees at the university, he bore an active part in the civil war, and made one of a party of horse which conveyed the college plate and a small supply of money to Nottingham, where the king had set up his standard. He also published a tract against the covenant, which was so offensive to persons in power, that he was obliged to retire to London, where he rendered all the service in his power to the royal cause. As he possessed talents that justified confidence, he was employed on various occasions of importance by the king and his friends; and he seems to have been successful in his endeavours to reclaim some persons who had been induced to abandon the cause to which he was devoted. During his majesty's confinement in Carisbrooke castle, Mr. Barwick contrived to preserve for him a free intercourse with his friends; and he also concerted a plan for his escape, which however did not succeed. After the king's death, and when the royal cause seemed to be desperate, Mr. Barwick, though in a very weak state, exerted himself in maintaining a daily correspondence with the ministers of king Charles II. This office he was at length obliged to devolve, first on his brother Dr. Peter Barwick, and then on another of his brethren, whom he endeavoured to reserve, at the hazard of his own life, from the danger to which he was exposed in consequence of a treacherous discovery. When Mr. Barwick was threatened with torture if he did not immediately disclose the names of the persons who were concerned with him, he kept the secret with invincible firmness; upon which he was committed to the Tower by an order of council, dated April 9th, 1650. Here he was confined in a close dungeon, and debaamed the use of pen, ink, and paper, and of all books except the bible. In this situation he remained many months, during which his diet was herbs or fruit, and water-gruel made of oatmeal or barley, with curdled boil in it, and sweetened with a little sugar; and yet such was the benefit which he derived from this slender diet, that though he was afflicted with a phthisis, atrophy, and dyspepsia, when he was committed, he recovered beyond all expectation, and grew plump and fat. This fact has been mentioned by many physicians, as a proof of the advantage of temperance, even in the most invertebrate diseases.

After two years' confinement, he was discharged in 1652, upon giving security to appear at any time within a twelvemonth before the council of date. At the expiration of the year, being satisfied by president Bradshaw, who had been dismiffed by Cromwell, that neither he nor his friends would be exposed to any danger from the recognizance into which they had entered, he again engaged with ardour in public business, and conferred with several persons whom he had drawn over to the king's service, on various schemes for restoring monarchy. He was also employed in conducting the king's correspondence, which he did with fidelity and success; and when a restoration was likely to take place, he was sent over by the bishops to represent to the king the state of ecclesiastical affairs. On this occasion, he was received with expressions of cordial esteem by his majesty, and appointed one of his chaplains. Upon his return, he visited the university of Cambridge, and took the degree of Doctor in Divinity. Upon the king's restoration he was offered a bishopric, which he declined accepting, that the world might not imagine that his extraordinary zeal for episcopacy was owing to any secret hope he might indulge of being made a bishop. Up in this he was promoted to the deanship of Durham, with which he kept the rectory of Houghton le Spring, four miles distant from the city. The revenue which he thus acquired, he liberally employed in repairing public buildings, relieving the poor, and maintaining hospitality. In 1661, he took possession of the deanship of St. Paul's; and by his interest with his majesty he obtained two royal grants; one for the repair of the cathedral, to which he himself contributed; and the other for securing its privileges. The king also appointed him one of the nine assistants to the twelve bishops employed in the Savoy conference; and he was unanimously chosen by the clergy in convocation, their procurator. His various engagements brought on his old complaint, which was aggravated by renewed application after a temporary respite, and which terminated in his death, Oct. 9th, 1662. By his will he bequeathed the greatest part of his estate to charitable uses. As his time was so much devoted to political and public matters, we may well imagine that his writings were not numerous: they consisted only of three sermons: the piece against the covenant already mentioned; and the life of the bishop of Durham, annexed to his funeral sermon. Many of his letters to chancellor Hyde may be found in Thurloe's Collection of State Papers. Biog. Brit.

BARYGAZA, in Ancient Geography. See Barach.

BARYGAZENUM PROMONTORIUM, a promontory of India, placed by M. D'Anville at the south entrance of the "Barygazenus Sinus," or the present gulf of Cambaya.

BARYPYCNUM, in Greek Myth. The ancients gave this epithet to five of the eight flable or fixed founds of their diagram; namely, the hypate hypaton, the hypate monon, the monon the para to, and the para dize menon. These four terms, barypycnume, metaphore, parade, and derdile, imply the lower fixa or dense founds; that is to say, the fixa or coarse intervals, that mean of the fixa, the acme of the fixa, and the width of the fixa, meaning in the Greek metaphore the parhypate, the parhypate, the line, and the meta of the tetrachords of the fixa kind. By fixa or close, the intervals of the femitones in the chromatic and quarter tones in the enharmonic, are implied. See Greek System.

BARYTES, or ponderous earth; terra ponderosa, schwerde Germ., baryte, Fr.

The English and French names of this earth are derived from the Greek baryes, heavy, on account of the high specific gravity of the Ponderous Spars or native sulphate of barytes, which is the commonest form in which this earth appears.

§ 1. Historical notices respecting barytes.

It is to Scheele that Chemistry is indebted for the discovery of this substance in 1774. In his valuable essay on manganes, he informs us that the nitric and muriatic solutions prepared from the native black oxyd of this metal contain besides, an earth differing from all those hitherto known by its strong affinity for sulphuric acid, &c. In 1775 Gahn made his analysis of the ponderous spars, and found it to consist of the earth newly discovered by Scheele, and sulphuric acid. Bergman repeated and confirmed the experiments of these chemists, and named the earth Terra ponderosa.
BAR

A method of obtaining pure barytes.

The only way of procuring this earth in a state of sufficient purity for chemical experiment, is to expose crystallized nitrate of barytes in a platinum crucible to a moderate red heat till it becomes quite dry and has ceased to give out any vapours; the nitric acid will be wholly decomposed and volatilized, leaving the barytes behind in the form of a greyish white porous mass or fine adherent to the crucible. The nitrate of barytes is obtained either by dissolving the native carbonate of barytes in very dilute nitric acid; or by heating the native sulphate of barytes in a close crucible with charcoal, and thus converting it into sulphate of barytes and then treating this with nitric acid, which will dissolve the earth, and leave the sulphate behind. A much more economical way however of preparing this earth is mentioned by Bartyo (Ann. de Chimie, vol. 40). Take sulphate of barytes, pulverize it together with charcoal, and expose it for half an hour to a full red heat; by this means the greater part will be converted into sulphate of barytes. Pour boiling water on the mass, and a clear yellow liquid will be obtained by filtration; add to this solution of soda; and a copious white precipitate of carbonate of barytes, four times the weight of the soda employed, will be deposited. This being separated from the solution of sulphate of soda and washed repeatedly, is to be mixed with charcoal and again heated for half an hour; the carbonate will be or the greater part converted into effuse powdery carbon, and the barytes will remain in a crucible. By a short digestion in boiling water, and frequent filtration, a clear superfluous solution of barytes is obtained; from which, by evaporation, a white and fluffy, in a silver crucible, the pure barytes is readily obtained.

§ 5. Chemical and physical properties.

Barytes, or earths containing the metal stannous, are very white and compact; and, if used as a pigment, its powdery state cannot be avoided, and must always be very dirty, unless it is at a high temperature, or the ground earth is vitreous and adherent to the crucible. It is a hard earth, and is capable of being mixed with a piece of glass, if fused and partly volatilized, communicating a yellow color to the mass.

Its affinity for water is very considerable. When exposed to the air, it gradually imbibles moisture, swells, and falls to

pieces, attracting at the same time the carbonic acid of the atmosphere and becoming mild; hence the necessity of keeping it in dry well-lidded vials. When well dried, with a little water, it exhibits the same appearance as quinolite, but with greater gravity; the mass becomes white, is remarkably increased in bulk, and a large quantity of heat is evolved. If stirred up while wet with an additional portion of water, to the confluence of a small pile, it cools, and, as it cools the state of a field, makes up of confounded needle-like crystals; but this by exposure to the air becomes carbonated and falls into powder.

Water boiled upon pure barytes, is capable of taking up its weight of this earth; the greater part of which, when depoits by cooling, in flaker denate crystals implanted into each other, or by carrying on the process very slowly, in the form of compacted hexagonal prisms terminated by a feathery pyramid, and of a brilliant lustrous hue. These crystals are to be composed of 33 parts of water and 47 of barytes. By a boiling heat, it is completely dissolved, and at length the water being evaporated, a white powder remains, which is pure barytes. By mere exposure to the air, they become efflorescent, and the earth is found to be carbonated. They revolatilize about 82 per cent of water at the temperature of 10°. The fluid that remains after the expression of the crystals of barytes takes 47° of the earth in its own solution, and is called barytic watcr; improperly, barytes, or barytes. This solute is perfectly limpid and colorless, and possesses properties very analogous to lime water. By exposure to the air, it becomes covered with a crust of carbonated barytes; and this being removed or falling to the bottom, a fresh crust begins to be formed till the whole of the earth is thus separated from the water.

Barytes, like the other alkaline earths, combines with all the known acids; and the barytic fahs thus produced are for the most part readily crystallized, and are distinguished by the thing mutual affinity to their elements; sulphuric acid and in particular is diffused by it from every other combination.

Among the simple inflammables, phosphorus and sulphur appear to be the only ones capable of uniting with barytes. If alternate portions of phosphoric and pure barytes are put into a firing glass tube closed at one end and exposed to a red heat, the phosphoric melts, sublimes, and combines with the barytes that is in contact with it, in a very fine white mass of a metallic luster, the phosphuret of barytes. This substance, when broken up, exaltes a strong frits, and a dark, changes gradually by exposure to the air into phosphurate of barytes, and immediately decomposes, giving out phosphoric and hydrogen gas.

The affinity between sulphur and barytes is very considerable. Pure barytes digested in warm water with sulphur will take upon them a quarter of its weight of this substance; being then evaporated to dryness and heated red hot in a crucible, the result is a reddish yellow mass, or fleshy mass, fullphuret of barytes. Its properties have been very little examined into, on account of the great deal with which it is decomposed. Sulphuret of barytes has the remarkable power of attraction for water, is very volatile, and is thrown off when cold, but is still more so in hot water. In this case, however, a decomposition of part of the water is effected; the by said water ascending with a portion of its bubbles, and the oxygen with another portion. The two continuations of these, however, are very uncertain, and having been very investigated by Bartsch, we shall treat of them somewhat at large.

When phosphuret of barytes is thrown into hot water it immediately
immediately dissolves, the liquid becomes of a yellow colour and exhalas a strong smell of sulphur and hydrogen; a white earthy sediment is precipitated, and as the liquid cools, a con- siderable quantity of crystals either acicular, prismatic, or in plates, makes their appearance: which being dried by peurren between filtering paper becomes perfectly white. Thus sulphure of barytes by the action of water furnishes three chief products. 1. The earthy sediment is re- generated sulphur of barytes; being produced by the oxogen of the water combining with part of the sulphur into sul- phure of hydrogen, and this as soon as formed satirnuing itself with barytes. 2. The crystals are hydralsulphure of barytes, a salt remarkable for being the only one of the earthy or alkaline hydralsulphures that is soluble in being crystallized. It is very little soluble in water, is easily soluble in acid, and is decomposable by the mineral acids with extraction of sulphured hydrogenc gas. Barytes being produced in the decomposition of sulphure of bar- ytes, it may be made in the direct way by pouring sul- phure of hydrogen gas through a Woud's apparatus containing barytes diffused in water. 3. Besides the sulphur and hydralsulphure of barytes, there remains from the de- compition of the sulphure of barytes, a yellow liquor, which, by the addition of muriatic acid, gives out a large quantity of sulphured hydrogen, and yields at the same time a copious precipitate of sulphur: hence it appears to be sulphure of barytes, intimately mixed or more probably combined with sulphured hydrogen.

There are therefore three modes in which sulphur can combine with barytes: the first is simple dry sulphure of barytes, soluble in water and without decomposition; the second is hydrosulphure of barytes, crystallizable, soluble in water and decomposable by muriatic acid without decomposing barytes; the third is sulphured hydrosulphure of barytes, soluble in water, not crystallizable, and when decomposed by muriatic acid giving out both sulphur and sulphured hydrogen.

Barytes, in consequence of its alkaline properties, acts on vegetable and animal matter with great energy: it forms indoluble soaps with oils, curdles and diffuses insoluble fibre, &c.

In the dry way, barytes diffuses flex in the same manner as potash does: three parts of barytes and one of flex being intimately mixed and fused together, produce a yellowish green mass entirely soluble in nitric, muriatic, or acetic acid, from which the flex may be separated in the usual way. In the moist way barytes being mixed with newly precipitated alumina makes a compound insoluble in water, but which is readily taken up by an excess of barytes.

Barytes diffuses certain metallic oxides, especially those of lead; but these combinations have not been much attended to.

Barytes was for a long time supposed to be a very refractory metallic oxide. Berzelius, Lavoisier, and other eminent chemists adopted this opinion from its great specific gravity, from the greenish hue that it communicates by fusion with the other earths, and from its being precipitable from its solutions in acids by prussic acid. But, in answer to these arguments, it may be remarked, that metals in proportion as they become exchanged approach to the state of acids; with rare barytes profit of alkaline properties in a very eminent degree: and that prussic acid, when quite pure, does not precipitate barytes; this appearance is being always occasioned by the presence of fulminate of potash, with which the prussic is generally contaminated.

Barytes is an active poison to animals; as are most of its salts. It is not in de use in the large way, but is of con- siderable importance in the laboratory as a test for sulphuric acid and an effectual reagent to separate this substance from all its other combinations.

The order of the affinities to which barytes is suilj close as far as they have been investigated, appears to be in the mord. way,—sulphuric acid, oxalic, ferrous, fluoric, phosphoric, fusco- locholic acid, nitric, muriatic, citric, tartaric, ascitic, hori- tic, boric, baryc, acetic, boric, sulphureous, arsenious, and prussic acids, water, fat ox, sulphur, alumin, fluid in the dry way,—phosphoric acid, boric, arsenic, sulphureous, fluoric, and muriatic acids, sulphur, oxygen of lead, and alumine.

Barytes is a very efficacious leeching in cases of indigestion, dyspepsia, and much other disease of the stomach. It is well known to be possessed with the power of precipitating phosphatic and all other metallic oxides, so as to separate them from the substance which has taken them up. By this means it is very serviceable in many cases of disease, and is the best leech cucumis has.
given in favour of births protracted to even more than twelve months, which Le Bas thinks might, and, he had no doubt, had happened. Bouvard and Louis, on the contrary, contending against the authority of these pretended cases of protracted gestation brought by their antagonists, which they do not admit to have been completely proved in any one instance, fix the time of parturition in women to nine calendar months from the time of conception; allowing it may be extended beyond that time ten or twenty days, and denying that in any one well-authenticated case, proof had been produced of a woman's being delivered of a living child later than that period. This opinion is now, we believe, universally established. The following are the titles of the books written by Le Bas on the subject:— Questration important: Peut on déterminer le temps de l'accoucheement? Paris 1794, 8vo. "Nouvelles Observations sur les naiffances tardives," 1795, 8vo; written in answer to Louis, who had confuted his arguments, and denied the authenticity of the cases brought in support of them. "Lettre à M. Bouvard, au sujet de sa derniere consultation," 1795, 8vo. Bouvard had taken the same side with Louis. "Réponse à un ouvrage de M. Bouvard," 1795, 8vo. This is written with much sincerity: the last recourse, when defending a bad cause. Hailer, Bib. Chimur.

**BAS**

**BAS,** in Geography, a small island in the English channel, near the coast of France, in the district of St. Pol de Leon, near Penpoul, the harbour of St. Pol, one French mile in length, and 1/4 of a mile in breadth: difficult and dangerous of access on account of the rocks overgrown with sea-weeds. The eastern part of the island is rather mountainous, but towards the west and north-west the coast is lower, and well cultivated. The whole population comprehends about 800 persons, who inhabit three villages, viz. Forêt-de-Neve, Carn, and Gouslès. The island is defended by four batteries and two forts, with eleven pieces of cannon and 80 canoneers, besides a garrison of 50 men to guard the coasts. It has only one spring of water: the soil is sandy: the men are all sailors, and the women cultivate the ground. The richest proprietor here does not possess more than six or seven cows, of which there are only about 200 on the whole island. Not a single tree grows here. The isle abounds with fish. The inhabitants live together in fraternal concord, and consider themselves as members of one family. N. lat. 52° 50′; W. long. 4° 17′. This is the fairest of a bar which runs in eastward from Quiberon bay on the south of Vilévre river, on the west coast of France.

**BAS en Béjíca.** A town of France, in the department of the Upper Loire, and chief place of a canton in the district of Yvilleaux; one league north-west of Montluel. The place contains 5686 and the canton 11,173 inhabitants; the territory includes 20747 square miles and six communes.

**BAS Relief.** See Basso relevé.

**BASAAL.** In Botany, the name of an Indian tree, growing about Cochin and Reya's Hill.

**BASAG.** In Ancient Geography, an island of the Indian ocean near Arabia Felix, according to Pliny.

**BASALT, artificial, or black porcelain; a composition having nearly the same properties with the natural basalt, invented by Meisser, Wedgwood and Bentley, and applied to various purposes in their manufactures.**

**BASALT.** In Mineralogy. Argilla basaltice, Werner; figurate trap of Kirwan.

The colour of this mineral is generally greyish black, or more rarely bluish or brownish black: its surface is usually reddish brown, from a partial decomposition. It is found in large masses, comprising entire insulated mountains of a somewhat conical form. Of itself it is definite of figure, but not infrequently contains flinty particles of olivin or basaltic hornblende: its fracture is uneven, falling into fine splinters, sometimes approaching to the even or flat conchoidal. It flies, when broken, into indeterminate rather sharp-edged fragments.

The most usual form of basalt is that of columns, straight or curved, perpendicular or inclined, from three inches to three feet in diameter. These pillars are divided either by horizontal joints at right angles to their axes, or by articulations formed by the convex end of one piece inserted into the concave extremity of the adjoining one. The forms of the columns are pentagonal, hexagonal, octagonal, rarely triangular or quadrangular. Basalt also sometimes occurs in tables, or globular or elliptical concentric masses, called by the French basaltite en boules.

It gives a clear ash-grey streak, is almost hard enough to give fire with flint, and is very difficultly broken. It is generally opaque, though sometimes slightly translucent on the edges. It is remarkably obscure when struck with the hammer. Sp. gr. according to Bergman, 31 Briffon, 2.864. It is somewhat magnetic.

Before the blowpipe, basalt fuses without addition into a black opaque glass, attractive by the magnet. When heated in a charcoal crucible, according to Klaperoth, it fuses into an ash-grey mass of a dull earthy fracture, and minutely spongy texture, overlaid with grains of iron: it fuses in this proceeds 9 per cent. of its weight. In a clay crucible, it fuses into a dense glass, opaque in mass, but transparent, and of a clove-brown colour, in thin splinters.

Its constituent parts, according to Bergman, are:

- Silica — 50
- Alumina — 15
- Lime — 8
- Magnesia — 2
- Iron — 25

The geological characters of basalt, and the various controversies with regard to its origin, and that of the other Rocks of Secondary Transformation, will be treated of at large in their proper place. It will be sufficient to mention here, that basalt belongs to the stratified mountains, and that it very rarely contains any petrifications. When in mass, it never includes any metallic veins; and when it occurs in the form of dykes, in coal strata or metalliciferous rocks, it produces a total separation of the ore or coal on each side of the dyke.

It is seldom if ever quite pure, being generally mixed with basaltic hornblende, common hornblende, and olivin; more rarely with zonite, felsipar, quartz, feshor, and calceous spar. Aicna is sometimes found on its surface, though very seldom penetrating its substance. When mingled with these in considerable proportion, it is easily decomposable into a remarkably fertile clayey loam.

The north-east coast of Ireland presents the most perfect and magnificent ranges of basaltic columns in the world: the celebrated Giants' Causeway is an assemblage of many thousand articulated pillars projecting into the sea, at the foot of a lofty basaltic promontory, exhibiting a polygonal pavement somewhat resembling a solid honeycomb. The promontory at Fairhead is a vast colonade of upright basaltic pillars, the shafts of which are 250 feet in length. Scotland also contains many beautiful specimens of columnar basalt; the little island of Staffa in particular almost entirely consists of basaltic pillars, both vertical and bending. The central district of Auvergne in France, and the northern parts
parts of Italy at the foot of the Alps, as well as Saxony and Hesse in Germany, are also remarkable for their tufatic columns.

Besides the use of tufa as a material for building and paving, it has of late been employed as an ingredient in the manufacture of glass bottles; it serves instead of more costly substances, and the glass, though black and opaque, has the advantage of being considerably stronger than the common green kind. When calcined and pulverized, tufa is an excellent substitute for puszolana in the composition of mortar, to which it gives the property of hardening under water.

BASANITE of Kiriwa, in Mineralogy. See Siliceous Schistus.

Basanites, in Natural History, a name given by many authors to the touchstone, used for trying gold, &c. They speak of a basaltine which yielded a bloody juice, and was good against druses of the liver.

 BASANTUS Lapis, in Ancient Geography, the name of a mountain in Egypt, according to Ptolemy.

 BASANUS, in Natural History. See Touchstone.

 BASARA, in Ancient Geography, a town of Palestine, in Galilee, 20 miles from Gaba, in the vicinity of Ptolemais. Josephus.

 BASARTSCHIK, in Geography, a confederate town of Romania, in Turkey of Europe. It is tolerably well built, has broad and clean streets and good trade, and is seated on the river Maritz. N. lat. 40° 40'. E. long. 24° 31'.

 BASARUCO, in Communes, a small base coin in the East Indies, being made only of very bad tin. Of this coin there are two sorts, good and bad; the value of the base fort is 1/4 less than that of the good. Three basarucos are equal to two rees of Portugal.

 BASCANIA, in Antiquity, ridiculous or grotesque figures hung up by the ancient smiths before their furnaces, to divert envy.

 BASCARA, in Geography, a town of Africa, in Biskulverg. The soil in its vicinity is fertile in grain and fruits, particularly dates, which are excellent.

 BASCHARGE, a town of France, in the department of the Forêts, and chief place of a canton in the district of Luxembourg. The place contains 8,38 and the canton 9,422 inhabitants; the territory includes 245 kilometres and 13 communes.

 BASCINNO, a town of Italy, in the kingdom of Naples, and province of Abruzzo Ultra, 4 miles S.S.E. of Parma.

 BASCULUMBAY, a town of Asia Minor, in the province of Natolia; 30 miles east of Pergamo.

 BASE, Basis, in Architecture, denotes an assemblage of mouldings constituting the lower part of a column, of a pier, or of a pediment.

In the Grecian remains of the Ionic order, the lower torus, astragal, or fillet of the base, rests immediately under the upper step of the building; but in those of the Corinthian order, a square plinth is added to the base. This practice is observed in all the Roman works, with the exception of the temple of Vesta at Tivoli and at Rome; small circular mouldings, in which a plinth radiating to the centre would have had an unpleasing effect. Modern architects have universally given plinths to their bases; and the following rules may be deduced from their works: the height of the first bases of columns to be half a diameter, those of pedestals, two-thirds of the height of the respective column and pedestal; the plinths of the Tuscan and Doric orders, one-half the height of the base; and one third in the Ionic and Corinthian. For the particular proportions of the mouldings, we refer to the plates.

The Attic or Atticurgic base consists of two toruses and fillets, with an intermediate scotia. (See Pl. XVII. of Architecture; and Pl. I. fig. 1, from the temple of Jupiter Olympius at Athens; and figs. 2, from the temple of Minerva Polias, of the same place.) This base, probably the most ancient of any, is employed in all the Athenian remains of the Ionic and Corinthian orders; in Roman antiquities, it is frequently used in the Corinthian order, and confidedly in the Ionic; and it has been adopted in every order by modern architects. It may be observed in this place, that, of the Grecian Ionic bases, the upper torus is frequently fluted. See Pl. 1. fig. 2. Plate XXVIII.

The Tuscan base. The remains of antiquity do not furnish any complete specimen of the Tuscan order; and modern architects have accordingly varied in this order more than in any other; the base, however, has been determined by all to consist of a fillet and torus. See Pl. XIV. of Architecture.

The Doric base. It has been the practice of antiquity to execute the Doric order without a base. The majestic strength of this dignified order required no additional flabbity from a base, the projecting mouldings of which would have embroiled the comparative narrowness of the non-triglyph intercolumniation. But modern architects having adopted a column modelled rather on Roman than Grecian proportions, have for the most part, with great propriety, added a base to their slender order. The Doric base invented by Vitruvius (see Plate I. fig. 3.) consists of a fillet, astragal, and torus; all other architects have used the Attic base.

The Ionic base. The base peculiar to this order, as described by Vitruvius (see Plate I. fig. 4.), consists of a torus and fillet resting upon two scoties, divided by astragal and fillets. On this base there is an example in the remains of the temple of Minerva P at Priene. (See Pl. XXVIII.) However, the practice of ancient and modern artists, with few exceptions, has given the Attic base to this order.

The Corinthian base (see Plate XXIX.) differs from the Attic, in having two scoties with astragals between the torus. This base is found in the Pantheon, and in the columns of the Campo Vaccino. In the other Roman and in the Grecian antiquities of this order, the Attic base is employed.

The Composite base. The composite order has no peculiar base, and uses the Attic and Corinthian bases in different. Vitruvius, Stuart's Athens. Deh. des. de Rome. Arch. di. A. Pallado. Regno di J. B. da Vignola. Base, Radiers, that has its statures cut like cables. Base, in Fortification, denotes the external side of the polygon, or that imaginary line which is drawn from the flanked angle of a bastion to that which is opposite to it.

Base of a Figure, in Geometry, denotes the lowest part of its perimeter; in which sense, the base stands opposed to the vertex, which denotes the highest part.

Base of a Triangle, is properly the lowest side, or that which is parallel to the horizon.

Thus, the line AB is the base of the triangle ABC.
B A S

Plate III. Geom. fig. 8. Not but, on other occasions, the line, AC, or BC in the triangle, may be made the base.

In a right-angled triangle, the F is perpendicular to the base; in the other, the other base.

Base, a fixed line, is known to be that on which it lies. Then the chord opposite B is the base of the cylinder, A图. Plate III. Geom. fig. 39.

Base, in &c. &c. is straight line to the hypothesis, and parallel to the central intersection of the several planes, and that of one side.

Base, in Heredity, reaches the bottom of the limb; and the charge that remains to be base.

Base Defined in Optik. Sec. Distinct.

Base of 3d Heart, in Anatomy, denotes the broader or upper part of it, which, to the sides of which is the two anterior, &c. The 4th motion of L. Newton's hypothesis, is the entrance of the water, &c.

Base, or Basis, in Chemistry, a term which was applied, by the old chemists, to designate those substances of a not-alkali, peroxide, combined with, and were acted upon, by more volatile or active meritit. Thus the alkaline earth, and metallic oxyd, which form compound salts by uniting with acids, were called the bases of these salts.

M. La Place, though they maintain that in every combination, the neuter form of alcohol between two ingredients is united and equal, have yet retained the term, for the sake of precision, to express either species or families of alkali, which differ with regard to the acid, but agree as to the alkali, earth, or metallic oxd which they contain.

Thus, salts with a base of porphyr, include all those species which are formed by the combination of the various acids with the particular alkali porphyr. Again, salts with an alkaline base comprehend the three families of salts with bases of porphyr, soda, or ammonia, as distinguished from the other salts with earthly or metallic bases. The utility, therefore, of this mode of expression is evident; for though the compound salts are usually divided into genera, according to their acids, as sulfates, nitrites, muriates, &c. yet it is often desirable to distinguish them according to their element or base, for which the Lavoisierian nomenclature has not particularly provided.

The term base is also used on other occasions as a method of denoting species; as when we say, sulfureous acid is composed of oxygen united with a base of sulphur: the vegetable acids of oxygen, and a compound hydrogen and carbon. Sometimes also the word base is applied in a more indefinite manner; as in the expression, phosphat of lime is the base of animal bone, azot is the base of muscular fibre: where it means the characterizing or principal part.

Base, Engl. Baso, Fr. Basso. Itali. in Musik, the lowest part in the harmony of a musical composition. We prefer the derivation of the word from bazo. Lat. to base, or basso; as the word bass is already naturalized in the use that is made of it in architecture, the base of a pillar. Sir Francis Bacon uses it musically for a deep or grave sound; "in pipes the lower the tone the baser, and the farther from the mouth of the pipe, the more base sounds they yield." Nat. Hist. No. 93. And Dryden thus expresses the string of an instrument that gives a base sound: "At thy we-harped'9 thumb from thore to skewer, The trebles squeak for fear, the bases roar."

Dr. Johnson says, base is applied to deep, grave sounds; it is frequently written base, though the comparative basset seems to require base.

The base is the most important of all the parts of polyphonic composition, being the foundation upon which all the other parts are built, and it has long been a maxim among musicians, that "in the base to be good, the harmony and modulation are seldom defective."

The word base is applied to various purposes in music; as base viol, principal base, continued base, ripieno base, ground base, thorough base, &c. most of which explain themselves: the rest will be further noticed in their places. But the base of a common chord or part of a chord, called by the Italians base principale, and by the French base fondamentale, is what we belong to this article, and requires an explanation of its own.

A principle or fundamental base, in practice, is that base which carries the common chord of 1st or the chord of the 7th.

In the Encyclopedic Methodique, there are rules given of M. Suzeur for arranging the parts to a low base, which M. Faurery says are excellent; yet he has nothing to object to every one of them. We find no dispute with either of those able musical critics, their rules or exceptions; we fear that both will be uneasiness to young composers, and that an experienced composer will hardly avoid a dictation for the arrangement of the several parts in his compositions. All we shall recommend to the young harmonist, or juvenile organist, is to accompany low notes in the base by wide intervals. In common chords, when the base is low in the scale, thirds have a very growing bad effect, particularly on the organ. In raising up the parts with the left hand, when the right hand has common chord divisions derived from common chords, the left hand should only give the fifth and eighth to the base. For the fundamental and supped base, to the trebl. scale, major, minor, and chromatic. See Counterpoint, Composition, Score, Common Chords, and Thorough-Bass.

Base Fundamental. The general acceptation of the term base, in practical music, has been given in the preceding article. We shall now endeavour to trace the history of the fundamental base in theory; which Rameau and his adherents regard as a discovery in music, equal to Newton's doctrine of gravitation in astronomy.

The earliest notice in England of the phenomenon upon which the fundamental base of Rameau has been built, was in the Royal Society, in a paper written by Dr. Wallis "on the trembling of conical prisms." Mar. 1767. N° 134. p. 839. Abridg. vol. 1. p. 666.

"I have long been observed, that if a violin-, or harp-string, be touched with the bow or hand, in another string on the same or another instrument not far from it (if in unison to it, or an octave, or the like) as at the same time tremble of its own accord. I can now add, that not the whole of that other string, but thus this string, and the several parts frequently, according as they are unison to the whole or the parts of the first for brackets." (Here he gives the several divisions into which a string, when caused to sound, divides itself, and a description of the forms of the several enlargements on a plate; but of these we shall have further occasion to speak hereafter.)

"This was first of all (as I know of) discovered by Mr. William Noble, M.A. of Eton college; and by him showed to some of our musicians at the same time since: and after him by Mr. Thomas Pigot, A.B. of Wadhams college,
college, without knowing that Mr. Noble had discovered it before. As we are now only proving a claim, we need cite no more of this paper; as the end of which another paper is referred to (N. Y. p. 874), which reference says: "Concerning the phenomena, an opinion is given by Dr. Narrodes, in Dr. Parr's Natural History of Oxfordshire."

D'Alambert (D'Alembert de Musique) speaks of Rameau as the discoverer of the harmonics, as we are other of the system built upon them. In the prose to the second edition of his Élémens de Musique, in which he has disserted and methodized the musical treatises of Rameau he says: "It was Rameau who first began to reduce chaos to order, and to throw a light upon the principles of harmony."

"He found in the forces of a single string or sounding body, the most probable origin of harmony, and of the pleasure which it affords us; he developed the principle, and showed whence the phenomenon of music were derived," &c.

And Rouffeau, D. R. Mofart. Harimics, says, that "Pere Merfenne and him uncou show having been that every found, though seeming a little simple, was always accompanied by other phenomena, in harmony, which formed with it the common chord major; and Rameau, setting off from this, and adding to it the parts of that harmonious system, which M. D'Alembert at length took the trouble of explaining to the world."
producing invisibly, and without human aid, the sweetest chord in the whole system of harmony.

Here all the phenomena are represented and explained, of kindred strings being caused to tremble and found merely by the tremors occasioned in the medium by the tone of a neighbouring string or sounding body.

Here too the theory of tuning strings, not only by tension but by weights, is explained; from which proportions, doubtless, the lurchchord of Plinius was tuned by weights instead of tension, some fifty years ago.

Having justly referred to Galileo the discovery of the harmonic proportions into which every single string or sounding body divides itself when caused to sound, it seems unnecessary further to explain this phenomenon here. We shall therefore proceed to the system built on this foundation by Rameau, under the title of Bassa Fundamental; concerning which, not only the author, but the French nation, have glowed as much as if he had discovered and conquered a new world in the celestial regions of harmony.

Bassa Fundamental, or Fundamental Bases, was first formed into a system by Rameau, and though the Italians meant the same thing by basso principe, so early as the time of Zarlinio, it was not so clearly explained; nor were

in a regular ascent or descent of the scale in modern harmony, the rule for accompanying the octave (see Regle de L'Octave) allows only common chords to the key note and the 5th of the key; which are consequently fundamental bases: the chords of the 6th and 9th are given to the root.

Rameau (Traite de l'Harmonie, p. 190.) has made all the following bases fundamental, by accompanying them with common chords.

By contrary motion, however, the principal base may have, and often has had, common chords with good effect, when ascending diatonically.

And if the seventh were added to many of these chords, they would be still more interesting, without divelling the base of the title of fundamental.

Of all the experiments that have been made in physical harmony, there has been no satisfactory origin found of

its derivation or derivatives, from a physical experiment, then generally known in Italy.

The natural harmony or common chord to every base, consists of the third, fifth, and eight above the base; or their octaves, which the Germans call the triad: or rather the unison, or any given found, with its third and fifth, constitute their triad, without the octave. If instead of the fundamental or lowest found (which Rameau calls the generator) the base takes the third or fifth of that chord instead of the lower found or principal base, the harmony is said to be inverted; and the lowest part, carrying the chord of the sixth, or & 9, is called the supponed base, and sometimes the base continuo. (See Supposed Base, and Basso Continuo.)

If any found is added to the common chord, except the seventh, the base is no longer fundamental.

The fundamental base should move by constant intervals, as 2d, 4th, 5th, or 6th; nearer rising or falling one note or degree with perfect and similar harmony to both; as it would occasion a violation of the rule against 5ths and 8ths in succession, and preclude all relation and connection of chord to chord. Common chords may be given to the following fundamental bases in succession.

By contrary motion, however, the principal base may have, and often has had, common chords with good effect, when ascending diatonically.

And if the seventh were added to many of these chords, they would be still more interesting, without divelling the base of the title of fundamental.
this origin neither satisfied theorists nor practical musicians. And in M. D'Alembert's second edition of his "Elements" he changed his ground, and instead of the chord minor of F,

he adopted that of C: \[ \begin{array}{c}
\text{F} \\
\text{G} \\
\text{A} \\
\text{B} \\
\text{C} \\
\text{D} \\
\text{E} \\
\text{F} \\
\end{array} \]

in which G is an

harmonic of C as well as of E♭. But this solution of the difficulty, fetched from far, and by no means satisfactory, was changed in the article "Fundamentals of the 7th volume of the Encyclopaedia, to A♭, without succeeding in proving it to be the work of nature.

The able Peyton in the new Encyclopaedia, I say, that F is the fundamental base of A minor. But though among the harmonics of a single base note there is, at the top of the chord, a found something resembling a 7th, it is not a major 7th; nor can F, or any grade found, produce a major 7th. All the harmonics produced by F, are the following, and in the following arithmetic order:

1 8 15 17 19 21 22.  F e f a c ¦ i.  1 3 5 6 7 8.

A major 7th may be joined to the common chord of F in practice, without taking from it the title of fundamental; but it is not one of its harmonics; e.g., F is not the fundamental base to A minor. Nor does nature give any indication of a minor chord either in the harmonics, or of found produced by two trebles. See Terra Suona.

Base-Viol. This instrument is now often confounded with the violoncello, though not of the same kind. In the 17th century every musical family had a chef de viol; all with six strings, and the finger-board fretted. The base-viol was the largest of these instruments, and called in England the six-stringed base; but in Italy, viol da gamba, on account of its reeling on the leg of the performer. The tenor viol, the next in size of that chef, is called viol da braccio, from its reeling on the arm or shoulder when played on. The smallest and highest of these instruments is called the treble viol.

A complete chef of viol contains eight instruments; two first trebles, two second trebles, two tenors, and two basses; all flowering and tuned alike, by 4ths and 3rds, and the necks fretted. The accordance of the open strings is as follows.

Treble Viol.

Tenor Viol;

or, Viol da Braccio,

Base Viol;

or, Viol da Gamba.

From the time of queen Elizabeth till that of Charles II, in all private concerts (where none that were public then) these, except the common flute, were the only instruments that were admitted into a gentleman's house; and indeed from the feebleness of the tone they may very properly be called strummed da camera, chamber instruments. At first, where voices could not be procured, the several parts of full anthems, services, and other choral mus...
but by further examination of this interesting controversy, he became a firm believer of the truth of the divine million of
Christ, though he denied many of those doctrines which formed Christians deem to be essential articles of the Christian
faith. In 1749, he was appointed private tutor to the son of a gentleman in Holstein; in this situation he had an oppor-
tunity of submitting to the test of experience the plan of
an improved method of education, which he had for some
time held in contemplation. The attempt succeeded to his
wishes; and though his pupil was only seven years of age,
when he undertook the charge of him, he was able in the
space of three years not only to read Latin authors, but to
translate from the German into that language, and to speak
and write it with a degree of fluency. He had also made
considerable progress in the principles of religion and morals,
in history, geography, and arithmetic. This success advanced
his reputation: so that in 1752 he was admitted to the
degree of master of arts at Kiels, and in the following year
he was chosen professor of moral philosophy and the belles
lettres in the academy at Soroe in Denmark. Here he pub-
lished several works, which were well received; particularly
his "Practical Morality for all conditions," containing hints
of his improved plan of school education. His lectures
on morality and religion were much frequented; but as he
spoke with freedom on some points of theology that were
generally received, he was removed from the Danish court to
the gymnasium at Altona, and allowed the salary which he
had enjoyed as professor. In the 4th year of his age he
began, in opposition to the advice and remonstrance of his
friends, to attack publicly many received tenets of the church,
and he published his "Philately," in which he urges
bouts concerning the eternity of future punishment; his
"Methodical Instruction in Natural and Revealed Religion," in
which he avows his different from the common doctrine
concerning Jesus Christ, the Holy Ghost, inspiration, bap-
tism, the Lord's supper; &c.; his "Theoretic System of Sound
Reason," and some other works of a similar kind.
In consequence of these publications he was represented by
Gotze, Winkler, and Zimmermann, clergyman of Hamburg,
as holding opinions hostile to revelation, as a man void of
principle, and as an enemy to religion. The populace like-
wise were incensed, and threatened to stone him. He was
preferred, however, from becoming a victim to intolerance,
by the protection of count Bernstorf and some other friends
at Copenhagen. In these circumstances he directed his at-
tention to an improvement of the usual method of school-
education; and for his encouragement in the prosecution of
it, he was received by the Danish court from attendance at
the gymnasium of Altona, and allowed a pension of 350
dollars. Having solicited and obtained considerable sub-
scriptions, he published in 1759 the heads of his "Element-
ary Bank," which he submitted to the inspection of many
respectable and learned friends, by whom it was approved.
In 1771, the fund which he had collected amounted to
11,500 rix-dollars; of which a thousand had been contrib-
uted by the emperors of Russia, who read his plan and
invited him to Petersburg. Although he met with some op-
position, he obtained very considerable encouragement; and
he was invited by the prince of Delfau, with the promise of
a pension of 1500 rix-dollars, to establish the school which
he had projected in his territories. Accordingly, he removed
to Delfau, which afterwards became the chief place of his
residence. Having published several detached parts of his
work, he determined in 1772 to continue it. In the fol-
lowing year he published the principles of "Arithmetic and
the Mathematics," and in 1774 his grand treatise in four
volumes, with 100 copper-plates, under the title of "Ele-
mental Work," by way of distinction from his "Element-
ary Bank" which he had published in 1770. This publi-
cation was favourably received, and was soon translated
into Latin and into French. As he had betted six years' la-
bour on the completion of this work, his health declined;
and in this state he wrote his "Legacy for the Confidence,"
being a work on the principles of natural and revealed re-
ligion. The prince of Delfau, having permitted him to
establish his school in any place which he found most con-
venient, he travelled to Frankfort on the Maine; and on
his 51st birth-day, he determined to put his plan in execu-
tion, and, on account of his humane object, to give his fe-
munity the name of the "Philanthropium." This school was
intended to be a seminary for rearing up young teachers
and professors, and a pattern for all the other schools of
Germany. The children of wealthy parents were to be ad-
mitted for the sum of 350 rix-dollars per annum; all the
former errors in education were to be carefully guarded
against; and the children of poor people were to be educa-
ted in it also, either to render them fit for becoming teachers
themselves in schools of lower rank, or for being useful
servants in respectable families." At Delfau, whether Bade-
dow returned from Frankfort, on the 27th of December
1774, the 6th birth-day of the hereditary prince of Delfau,
he opened his "Philanthropium," appointing Wolke as
head master, and undertaking the direction of it for seven
years, promising to read lectures, and to give a few hours'
instruction daily to the pupils without any emolument.
The plan, however, was not encouraged agreeably to Bade-
dow's expectations, and he therefore relinquished it. His
disappointment and other circumstances led him to seek re-
lied from drinking, by which he impaired his health and in-
jured his reputation. In the melancholy period that elapsed
from 1778 to 1783, he employed himself in examining the
nature of pure Christianity; and whatever may be thought
of his peculiar opinions with regard to some of its doctrines,
it appears he had been a friend to truth, and a zealous ad-
vocate for religion and virtue. In 1785 he published a plan
by which children might be more easily taught to read, and
distributed 500 copies of it in various schools. His plan was
introduced by himself in two schools at Magdeburg, and it
succeeded to his wishes. Having experienced great friend-
ship at Magdeburg, he removed to this city towards the
close of his life, and died there in 1790 in the 67th year of
his age. Bafedow is represented by his biographers as a
man of acute judgment and penetration, and possessed of
great sensibility and a lively imagination. His works, which
relate chiefly to religious subjects or to education, amount
to upwards of 50 different treatises. Beytrag zur Labern
geschichte, &c.; or Biographical Anecdotes of Joh. Berth.
Bafedow, taken from his own works, and from other authen-
tic sources, 5vo. Magdeburg, 1791.

BASELIECE in Geography, a town in Italy, in the kingdom of Naples and province of Capitanata, 7 miles S.S.W. of Volturara.

BASELS, Basilius, in our Old Writers, a kind of coin abolished by king Henry 11. 1158.

BASELLA, in Botany. Lin. gen. 582. Reich. 413. Schreb. 520. Juss. 74. Gar. 126. Clafs and order, pentandria trigynia. Nat. Order of Holarctane; Artifices Joff. Gen. Char. Calyx none. Cor. siven-leafed, pitcher-shaped; two outer divisions broader, one within the rct, converging above, fleshy at the base. Stam. filaments five, tubulate, equal, falkened to the corolla, and shorter than it; anthers roundish. Pill. germ superior, febularia; styles three, filiform, of the length of the flaments; fligmas oblong, on one side of the tops of the styles. Per. corolla perma-

manent, closed, fishy, counteracting a berry. Seed, single, roundish.

Eff. Char. Cal. none. Cor. seven-lobed; two opposite divisions shorter, at length berried. Seed, one.

Species. 1. B. rubra, red Malabar night-shade, eucuta. Lin. h. t. Cuff. 39. Gandola rubra, Rumph. Amb. t. 154. f. 2. "Leaves flat; peduncles simple." It has thick, strong, succulent stalks and leaves, of a deep purple color; climbing to the height of eight or ten feet, and producing many side-branches; in the dark-flower living through the winter, and producing great quantities of flowers and seeds. The fruit is a sort of loquorius berry, of a very dark red color, a little flattened, furrowed cross-wise at top, and containing a single nut. A native of the East Indies, Ambhina, Japan, &c.; and cultivated, in 1759, by Miller. From the berries a beautiful colour is drawn, but when used for painting, it changes to a pale colour; the juice is said to be used for staining calicines in India. 2. B. alba, white Malabar night-shade, Gandola alba, Rumpin. Amb. Prol. Alm. 143. f. 1. Murafkiki, Kamof. Amun. 78. The flesh firm, the leaves obtuse and flat, and the flowers and fruit smaller than in the foregoing. Miller raised from seeds, let by Juffuca, two varieties; one with the purple leaves and stalks, the other having leaves variegated with white. Cultivated by him at Compton in 1691. A native of China and Ambhina. 3. B. indica, shining Malabar night-shade: "leaves subcordate; peduncles crowned, branching." A native of the East Indies. 4. B. nigra, black Malabar night-shade; "leaves round-ovate; spires lateral." Stem perennia, trailing, slender, round, succulent, branched; leaves thick, smooth, entire, alternate, petiolate; flowers purple and white, lateral, f. w. in long, solitary spikes. Cylia three, roundish, acuminata, very small scales; corolla one-petalled, with a short swelling tube, and a five-leafed border; germ four-lobed; styles shorter than the filaments; berry roundish, deep black, small, four-lobed, with four blunt concave clefts at top. Lordrio apprehends, that the berry is formed from the germ, and not from the corolla. He thinks that this plant is the same with the "Gandola alba" of Rumphius; but different from the B. alba of Linnaeus. Perhaps none of these are specifically distinct. A native of China and Cochin, in the hedges and fences of their gardens.

Propagation. These plants are propagated by seeds, sown on a hot bed in the spring, and planted, when fit to remove, in a separate pot, filled with rich earth, and plunged in a warm bed, where they must be treated like other exotics. They may also be propagated by cuttings, which should be laid to dry for a day or two after being separated from the plant, before they are planted, that the wound may heal; other wise they will rot. These should be treated in the same manner with the feeding plants. These plants flower from June to autumn, and the seeds ripen in September and December. Martyn's Miller's Diet.

BASELLI, BENNET, in Biography, son of Mark Baelke, physician of Bergamo, a town in the Venetian territories, studied anatomy and medicine at Padua, asfifed by Fabricius ab aqua pendente, and other celebrated masters, under whom he is said to have made great proficiency in the knowledge of his profession. Returning to Venice in 1594, he was refused admission into the college of physicians there, on account of his practising surgery jointly with medicine. Irritated by the injustice, as he thought it, of the law by which he was rejected, he published at Bergamo, in 1624, a defence of surgery, under the title of "Apologie, qua prae chirurgice nobisater lintens pugnavit, libri tres, 4to. Elyay. Diet. Med." BASEMENT, in Architecture. Stereobata. Stylobata. Soubasement, Fr. The lower part or story of a building when it is in the form of a pedestal, with a base or plinth die, and cornice or plat-band.

In the Roman antiquities, the temples are generally raised on a basement which has exactly the members and proportions of a pedestal to the columns of the portico; but in modern architecture, the basement constituting the lower story of a habitation has its proportions regulated by the nature of the apartments which it contains. The Italian palaces have frequently the summer habitations on the basement, which in that case is often as high as the principal story; but when it only contains offices, it sometimes does not exceed one half of that height. These proportions may be considered as extremes, which it will not be proper to exceed; for the principal story loses its importance when too much elevated, while a very low basement will not admit any tolerable proportions of windows and doors.

Basements are commonly decorated with reliefs of various kinds; they are crowned with a cornice or plat-band, and supported on a base or socle. The height of the reliefs, including the corn, should never be less than one module of the order of the principal story, neither should it exceed this measure; the plat-band should be the same height, as a rule, and the socle or plinth rather more. When the basement is furnished with a cornice, it should, also have a regular moulded base; the height of the cornice may be about one seventeenth of the whole basement, and the socle about twice as much. Chamber's Civil Architecture, Defiguris, etc. ed. de Rome.

BASENTELLE, in Geography. A town of Italy, in Calabria, where the emperor Otto II. was vanquished and made prisoner.

BASHARIANS, a sect of Mahometans, being a branch or subdivision of the Motazzites.

The Basharians are those who maintain the tenets of Balhar Ebn Motamer, a principal man among the Motazzites, who varied, in some points, from the general tenets of the sect, as extending man's free agency to a great length, even to the making him independent. He asserted, that God is not always obliged to do that which is best; for that, if he pleased, he could make all men true believers. Accordingly he taught, that God might doom an infant to eternal punishment; but taught at the same time, that he would be unjust in so doing. These sectaries also held that if a man repent of a mortal sin and afterwards return to it, he will be liable to suffer the punishment due to the former transgression. Vide Sale's Priscian. Dife. to the Koran, p. 162.

BASHAUF, Basha, or Pacha, a Turkish governor of a province, city, or other district. The Arabs pronounce it Balshu; but the word is Turkish, and properly Pashaw, denoting viceroy; whence is derived Pacha. As some of the provinces of the Turkish empire are too extensive for the government of the Pacha, this officer has a variety of subordinates; but it is in reality the sultan who dictates and commands, under the varied names of Pacha, Motfàlam, Kaim-Makam, and Aga; nor is there one in this descending scale, even to the lowest Deliba, who does not represent him.

All Egypt is, on the part of the grand signor, governed by a bashaw; who has in reality but little power, but seems principally to be meant for the means of communicating to his own persons, and to the orders of the several military agias (that is their bodies), the orders of the grand signor, and to see that they are executed by the proper effectives.

When Seim, sultan of the Ottomans, put a period to the dynasty of the Mamouks in 1517, he was sensible that
if he established a pacha in Egypt with the same authority which was possessed by the pachas in other provinces, the distance from the capital would be a strong temptation to revolt. For preventing this inconvenience, he projected such a form of government, that the power being distributed among the different members of the state, should preserve such an equilibrium as should keep them all dependent upon himself. The system of the Mamlouks who had espoused his first cause, appeared proper for this purpose; and he next established a divan or council of regency, composed of the pachas and the chiefs of the seven military corps. The office of the pacha was, as we have observed, to notify to this council the orders of the Porte, to expedite the tribute to Constantinople, to watch over the safety of the country against foreign enemies, and to counteract the ambitious views of the different parties. On the other hand, the members of the council possessed the right of rejecting the orders of the pacha on affixing their reasons, and even of deposing him; and it was necessary that they should ratify all civil or political ordinances. It was also agreed, that the 24 governors or bays of the provinces, should be chosen from the Mamlouks. This form of government has not ill corresponded with the views of Selim, since it has eluded about two centuries; and within the last 70 years, the porte has relaxed its vigilance, innovations have taken place, and the power of the Mamlouks has superseded and almost annihilated that of the Turks. In order to retain the pachas, the porte had conferred the divan to extend its power, till the chief of the Janizaries and Azabhs were left without control. Hence Ibrahim, one of the Kiyas, or veteran colonels of the Janizaries, about the year 1746, rendered himself in reality master of Egypt; and the orders of the sultan vanished before those of Ibrahim. About the year 1766, Ali Bey (see Ati Bey) rendered himself absolute master of the country. Since the revolution of Ibrahim Kiyas, and the revolt of Ali Bey, the Ottoman power has become more precarious in Egypt than in any other province; so that though the porte still retains there a pacha, this pacha, confined and watched in the college of Cairo, is rather the prisoner of the Mamlouks than the representative of the sultan. He is deposed, exiled, or expelled step by step, and on the mere summons of a herald clothed in black, called "Cezaronluk," he must defend himself from his high station, or be deposed. Some pachas, chosen expressly for that purpose by the porte, have endeavored by secret intrigues to recover the power formerly annexed to their title; but the bays have rendered all such attempts to dangerous, that they now submit quietly to their three years' captivity, and confine themselves to the peaceable enjoyment of their salary and emolument.

After Sultan Selim I. had taken Syriah from the Mamlouks, he felt that province, like the rest of the empire, to the government of pachas or vicars, as the term signifies. (See SYRIA.) But the province the pacha, being the image of the sultan, is, like him, an absolute despot. All power is vested in his person; he is chief both of the military and of the finances, of the police and of the criminal justice. He has the power of life and death; he has the power of making peace and war; and in a word, he can do everything. Tho' powers in their unlimited extent belong only to the pacha with three tails. The power of the pacha with two tails is not so considerable, for his department to extensive; he cannot put any one to death without a legal trial; he is, like another, chief of the armed force of his department; but when he takes the field, he is obliged to unite his standards to those of the pacha with three tails, and to march under his orders. The main object of such power vested with the pacha, is to collect the tribute and to transmit the revenue to their master. This duty fulfilled, no other is required from him; the means employed by the agent to accomplish it is a matter of no concern; those means are left to his discretion; and such is the nature of his situation, that he cannot be delicate in his choice of them; for he can neither advance, nor to the four corners, but in proportion as he can procure money. The place he holds depends on the favour of the viceroy, or some great officer; and this can only be obtained and secured by bidding higher than his competitors. He must therefore raise money to pay the tribute, and also to indemnify himself for all he has paid, support his dignity, and make a provision in case of accidents. Accordingly, the first care of a pacha, on entering on his government, is to devise methods to procure money, and the quickest is invariably the theft. The established mode of collecting the miri and the customs, is to appoint one or more principal farmers. For the current year, who, in order to incutate the collection, divide it into left farms, which are again subdivided, even to the smallest villages. The pachas let these employments to the biil bidder, wishing to draw as much money from them as possible. The farmers, whatever their fate have no object in taking them but easy,

strain every nerve to augment their receipt. Hence an ability in these delegates always bordering on dishonesty; hence those extortions to which they are the more easily inclined as they are free of being supported by authority; and hence, in the very heart of the people, a faction of men interested in multiplying impositions. The pacha may applaud himself for penetrating into the most hidden sources of private profits, by the clear-sighted capacity of his subalterns; but what is the consequence? The people, denied the enjoyment of the fruit of their labour, restrain their industry to the supply of their necessary wants. The husbandmen only knows to produce himself from staving: the smith labours only to support his family; if he has any surplus, he cautiously conceals it. Thus the arbitrary power of the sultan, transmitted to the pacha, and to all his subalterns, by giving a free course to extortion, becomes the main spring of a tyranny which circulates through every class, whilst its effects, by a reciprocal reaction, are everywhere fatal to agriculture, the arts, commerce, population; in a word, to every thing which constitutes the power of the state, or, which is the same thing, the power of the sultan himself.

This power is not subject to less shifts in the army. Perpetually urged by the necessity of obtaining money, on which its safety and tranquility depend, the pacha has resorted, as far as p. like, the usual military establishment. It diminishes the number of his troops, leaves them poor, winks at their disorder: and discipline is no more. It sometimes happens that the pachas, who are followers in their provinces, have personal hatreds against each other. To gratify these, they avail themselves of their power, and wage secret or open war; the various consequences of which are sure to be felt by the subjects of the sultan. It also happens that these pachas are tempted to appropriate to themselves the power of which they are the depositaries. The porte, in order to counteract their ambitious views, often changes the residence of the pachas, that they may not have time to form connections in the country; but as all the consequences of a bad form of government have a mischievous tendency, the pachas, uncertain of to-morrow, treat their provinces as mere transient possessions, and take care to make no improvement for the benefit of their successors. On the contrary, they listen to exhaust them of the produce, and to reap in one day, if possible, the fruit of
of many years. It is true, these irregularities, every now and then, are punished by the low-draw, one of the practices of the petty which bell displays the spirit of his government. The only sensible reason is always for having oppressed the subjects of the basin by the ports, by taking possession of the wealth of the extortioner, and resorting nothing to the people, leaves sufficient room to think that the government is far from disapproving a system of robbery and plunder which it finds so profitable. Every day, therefore, affords fresh examples of oppressive and robbery practices; and if none of them have hitherto succeeded in forming a stable and independent government, it is left owing to these wise measures of the divan, and the vigilance of the Capidjis, than their own ignorance in the art of governing. The pachas regard nothing but money; nor has repeated experience been able to make them sensible that this, far from being the pledge of their security, becomes the certain cause of their destruction. They are wholly devoted to amassing wealth, as if friends were to be purchased. As the pacha possesses the power of life and death, he exercises it without formality and without appeal. Wherever he meets with an offence, he orders the criminal to be seized; and the executioner, by whom he is accompanied, plunges him, or takes off his head upon the spot; now, sometimes he himself does not deliver this task. This duty he frequently commits to a deputy, called Wall. The administration of justice in civil suits is the only species of authority which the sultans have withheld from the executive power of the pachas. The officers appointed for this purpose are, by a wise regulation, all independent of the pachas. See Cani.

To the governors of provinces were formerly given indifferently the names of pacha and of beglerbeg, or beyler-bey; the latter at this day is reserved for the pachas of Bagdad and of Cutay; they have the pre-eminence over the other pachas, and generally command the troops which are brought into the field. The beyler-bey of Bagdad has under his orders the European troops, and the beyler-bey of Cutay those of Asia. They are nevertheless subordinate to the grand vizier, when the latter takes the general command of the armies. Formerly, the name bashaw, or pacha, was appropriated to such as had two children or horse-carriages before them; those who had the honour of three tails, called vizier-bashaws, were denominated begler-begos; and those who had only one, fand justoce.begos.

The appellation of bashaw is also given by way of courtesy at Constantinople, to the lords about the grand vizier's court, the officers in the army, and almost every person of any figure.

A bashaw is made with the solemnity of carrying a flag or banner before him, accompanied with music and fountains by the minstrel, an officer or purpOse for the investiture of bashaws.

Bashaw, used absolutely, denotes the prime vizier; the rest of the denomination being distinguished by the addition of the province, city, or the like, which they have the command of; as the bashaw of Egypt, of Palestine, &c. The bashaws are the emperors' pensioners. We find Lord complaints among Christians of their avarice and extortion. As they buy their governments, every thing is vended with them. Volney's Travels into Egypt and Syria, vol. i. ch. 10. vol. ii. ch. 33. Olivier's Travels in the Ottoman Empire, ch. 17. Roffia's Alepp, vol. i. p. 135, &c.

There are also fah-bashaws, or deputy-governors under the first. Phil. Trans. N° 218.

Bashaw, Captain, is the title of the Turkish high admiral, who commands the naval forces of the Ottoman empire, and is at the head of all the maritime establishments. He usually commands in person the fleets and all the naval forces of the empire; he nominates the captains and ensigns; he orders the building and repairing of ships; but the “Terfana-emini” is properly the naval minister, since he has the administration of the funds appropriated to the navy, the direction of supply of stores to the arsenals, and the care of the equipment of ships, and the superintendence of all the works. He has under him chiefs, deputys, and different harbour-masters, as well for the execution of his orders and for private superintendence, as for the police.

BASHEE ISLANDS, in Geography, a group of five islands situated in the Chinese sea, north of the Philippine islands, and south of Formosa. They are said to be so called by Dampier from the name of a liquor made of the juice of the sugar-cane and a small black grain, and used by the inhabitants. This name was given to the most easterly of the group, and at length was applied to them all. The productions of these islands are plantains, bananas, pine-apples, sugar-canes, potatoes, yams, and cotton; their quadrupeds are goats and hogs. The people, according to Dampier, are kind and hospitable. The names of the islands are Orange, Grafton, Monmouth, Isle of Goats, and Bashoo. This group is represented in the "Marine Voyage," p. 308. as consisting of five or seven islands; the northermost of which lies in N. lat. 42°. E. long. 122° 6'.

The two to the south-east are high lands; some of the others are of moderate height; the most northern except one is high and craggy at top; and between these two lie small rocks above water. Between these islands and that of Botol Tabac.-Xima, is a channel about 16 miles wide.

BASHEE, or Bashki, the most easterly island of the preceding group, appearing of a circular form, and being about 2 leagues in diameter. It has a town of the same name. N. lat. 41° 45'. E. long. 122° 15'.

BASCHIKIS, or Bashchieris, a people of the Russian empire. They call themselves Bashchieri; and derive their origin partly from the Nogis-tartars, and partly from the Bulgarians. Probably they are Nogys, whom the Bashares adopted among them: their country at least is a part of the ancient Bulgaria. They formerly roamed about the southern Siberia under the conduct of their own princes: to avoid the molestation of the Siberian khans, they settled in their present possession, spread themselves about the rivers Volga and Ural, and were subject to the Kazanian khanate. On the overthrow of that state by tsar Ivan II. they instantly took refuge under the Russian sceptre: they afterwards, however, frequently revolted against the government, whereby their prosperity as well as their population have been considerably diminished. In the year 1770, they consisted of twenty-seven thousand families, having their homes led in the governments of Ufa and Perme. The Bashchiers have been long without khan; and all their nobility have been gradually destroyed in the civil wars. At present every tribe or village touts for itself one or more ancients, or tarfchins; and the whole nation compose 34 wolofats. The huts or houses, which they inhabit during winter, are built after the Russian fashion; the principal part, which the family commonly po lishes, is furnished with large benches, which serve for beds; the chimney, of a conical form, and of the height of an ordinary man, is in the middle of this division, and long continued, that they are very useful for baking on this account. The Bashchiers are very subject to various complaints of the

In summer this people inhabit what the Russians call Jurtes: they are tents or covers of felt, which, like the huts, have several divisions and a chimney in the centre. A western village.
BAS

village contains from ten to fifty huts; but the summer encampment never exceeds twenty yurtes. These yurtes are a kind of hovels.

The Bashkirs have some knowledge of the art of weaving, and have looms; but it is from their own nation that they learnt their pride and the instructors of youth, they remain in the profoundest ignorance. With some knowledge of village, they retain a lining to the pastoral life; which spoils them for agriculture. They sow but little grain; consequently their harvests afford them only a few resources for the winter, being far from sufficient for their whole consumption. They apply with greater luxurare to the cultivation of bees; making hives in the trees to secure the purposes of hives which, to secure from the attacks of the bears, they have invented a variety of ingenious contrivances both as weapons and traps. One man, in frequent inspections, is known to pull off at least fifty hives. They have the art of finding out the mountains that contain mines; but, like the Tartars, they would think themselves disgraced by working them themselves. It must be owned, however, that they have not the strength of body which that labour requires.

Their practice is to let them out for a term of forty years to Russian contractors, assigning to them at the same time a tract of forest necessary for the forges. The poorest of them serve for wages in transporting the ore.

The women understand the art of weaving, fulling, and dyeing narrow coarse cloths; they likewise make the clothes for the whole family. They make a small quantity of linen of hemp; but they prefer weaving the filament of the common nettle, as that plant requires no culture, and the linen they make of it is extremely coarse. They have not the unwholesome practice of steeping their hemp or their nettle in water, but leave them to dry in the air on the top of their huts during the autumn and winter; then flapping off the bark, they pound them in wooden mortars. The men follow the more difficult business of making felt and of tanning leather. Both sexes wear shirts of the cloth made of nettle; they also wear wide drawers, which defeced to the ankle-bone, and a sort of slippers, like people in the East. Both men and women wear a long gown, that of the men being generally of red cloth bordered with fur; this they bind round their middle with a girdle, or with the belt to which they fix their semeinar. The poor have a winter pelisse of sheep skin, and the rich wear a horse skin in such a manner that the mane covers their back and waves in the wind. The cap is of cloth like the fruitain of a cone, and 10 inches high; and that of the rich is usually ornamented with valuable furs. The gown of the wives is made of fine cloth or silk, buttoned before as high as the neck, and fastened by a broad girdle, which the richer classes have made of steel. Their necks and throats are covered with a sort of shawl, on which are several rows of coins, or a string of flints.

The principal wealth of this people consists in their flocks; it is especially from their horses that they derive the necessities of life; meat, milk, vessels, garments. They have nearly as many and even rather more sheep than horses; and their horned cattle are about half as numerous; they likewise bring up some goats, and only the rich have camels. A man of the ordinary classes has seldom fewer than between thirty and fifty horses, many possess five hundred, and some a thousand, two thousand, and more. Their sheep are of the broad-tailed species; they esteem the others for the fine furs of their wool.

The most opulent of the Bashkirs are those who dwell to the east of the Urals, and in the province of Iriat. Some of them are owners of not less than four thousand horses, who fatten in the richest pastures: the wapas and goats oblige them in the month of June to quit their fine meadows, and retreat to the mountains: the horses then live their flesh and pine away, but regain their prime vigour on coming down again to the plains in the month of July.

Through the Bashkirs experience a long and very severe winter, yet they abandon their flocks and horses to the inclemencies of the season. They have neither granaries nor barns; they only lay up a little hay, which they range in cocks round the trees, referring it for the destitute cattle. The same that are healthy pick up a little grass or mors from beneath the snow, and are often reduced to the necessity of feeding on the bark of the young elms. No latter attention is paid to the camels, than to wrap them in some wretched coverings of felt which they few about their body. The cattle towards the end of the winter are become lean, weak, and emaciated. Though the flocks are never kept apart from the males, they rarely bring forth offspring; because the exhausted state of the flocks and herds during the winter, is unfavourable to generation. Neither the Bashkirs nor the Kalucks suffer the colts and the calves to fink their dams except during the night, their practice being to milk them in the day-time for their own advantage.

kumis, prepared from mare’s milk, being their favourite liquor. (See KUMIS.) They are also fond of a mixture of four milk and meal, called ARJAN. In the spring they drink the pop of the birch, which they collect by means of deep masons in the trees.

Their arms are the bow, the lance, the helmet, and coat of mail; from the Russians they obtain sabres, musquets, and pistols. A Bashkirian army presents a truly curious spectacle; observing no order in marching, they only form in ranks when they halt. Every one kindles a horse in his hand, which carries all his provisions: the hand however is not heavy; consisting only of cloth, shoe, care cloth dink in the kud, and a hand-mill to grind it to meal. With the meal they form a ball which they swallow, and which serves them for bread. Each warrior, drest in his long gown, equipped as he chooses or as he can. One has procured for himself the various kinds of arms, and carries a whole arsenal with him; the other fearcely pouffles more than one ill-conditioned weapon. Such troops as these render the armies of the ancient Persians at once so numerous and so little formidable.

They are all well mounted, are skillful in drawing the bow, and dexterously manage their horses. A small number of Bashkirs are easily victorious over a numerous squadron of Kirghises; sometimes one of their regiments will traverse a whole horde of Kirghises, put to flight by their very looks, and return triumphant without having fulfilled the slightest loss. The military service which they are bound to perform, and the only point in which they are called by the Russian yoke, consists in furnishing, in time of war, 3000 cavalry, which form 30 troops of 100 men each. The Bashkirsians are the most negligent and slovenly of the Tartars. In commerce they are the least intelligent; but, at the same time, they are the most hospitable, the most lively, and the most brave. Their diversions at any religious festival or at a marriage, consist in numerous libations of four milk, singing, dancing, wrestling, and horse-racing, in which they excel. In their songs they enumerate the achievements of their ancestors, or their own, and sometimes their amorous adventures. Their songs are always accompanied with gestures, which render them very theatrical. Among them age meets with the greatest respect. In their entertainments, it occupies the place of honour and the stranger, to whom compliments are paid,
is always flt among the old men. The language of these people is a Tartar dialect, very different from that spoken at Kafan. The Bakhtrians are, like most of the Tartars, Mahometans; but though they have their mosques, their madrasahs, and their schools, they are much addicted to fuf- ferition and forery. Their forefathers once gave even the devil, and pretend to engage with him in combat; and thus they delude the credulous vulgar, who consult them in their distress, and particularly when they lose any of their crop. Toole's View of Ruifi, vol. i. p. 473; Chantreaux's Travels, vol. i. p. 281.

BASIL or BASCHI, in Geography, a small town on a brook of the same name, at the distance of 4 German miles from the Culpeper fa.

BASHTIEN, Henry James Van, in Biography, a learned divine, was born at Hanau, in Germany, in 1792, and educated at Drewer, Leiden, and Franeker. In 1701, he was appointed professor of the oriental languages and ecclesiastical history in the gymnasium of Hanau, afterward professor of theology; and in 1712, he was elected member of the Royal Society of Berlin. He was afterwards professor of theology, the oriental languages, and history, in the gymnasium at Zerbit, where he died in 1758. About the year 1709, he established in his own house a printing-office, in which he printed many Hebrew and Rithmetic works. Among his writings are "Observ. Sac. lib. i. de integrat. Seer. Script." Frankf. 1708, 8vo.; "Comm. R. If Araban. in prophetem Mosis. &c." Hanov. 1710, fol.; "Difput. iii. de Nabitha vera & falsa," Hanov. 1710, 1711, 1712, 1713, 4to.; "Sylva Antiqu. Hebr. minus," Hanov. 1715, 8vo.; "Miscellanea Sacra, &c." Withe. 1719, 4to.; "Diff. de Idee, &c." Serv. 1719, 4to.; "Cumis Talmudicis," &c. Harau, 1742, 4to. Gen. Bibl.

BASIA ULTIMA. See Ulisma.

BASIA TRAIACI, in Botany, a name used by some for the common palagonium, or knot-grass.

BASCENTO, in Geography, a river of Naples, which rises near Potenza, in the province of Bulbiota, traverses this province, and runs into the gulf of Tarento. This is the ancient Metapontus, or Calyceum, on which Orestes Cesar and Mark Antony had an interview, brought about by the mediation of Octavia.

BASIL, Sr., denominated the Great, in Biography, was received in Baptism in the year 328 or 329. Having received instructions from his father in polite literature, he pursued his studies at Antioch under Libanius, at Cesarica in Palaestina, at Constantinople, and at Athens; in which latter place he formed an intimate acquaintance with Gregory Nazimius, and was introduced to Julian, afterwards emperor. In 355, he returned to his native country, and became a profiter of rhetoric, and a planker. His religious zeal, however, soon induced him to visit the monasteries in the deserts of Egypt and Lyby; and here his imagination was so transformed with the austerity of the devout nuns' ermites in these sequestered mansions, that he withdrew to a retired spot in the province of Pontus, and embraced the monastic life. He was soon joined by his brother and several friends, to whom he gave a set of ascetic rules; and he is regarded as the founder of all similar institutions in Pontus and Cappadocia. His monastic life continued, but not without some interruption by other avocations, for twelve years. Having been ordained priest by Eusebius bishop of Cesarica, he again withdrew to his solitude; but as his fame increased, he was elected to the see on the death of Eusebius in 309, 370, or 371. Here he succeeded Athanasius in the conduct of the Trinitarian controversy. Many attempts were made by the emperor Valens, who was an Arian, partly by friendly solicitations, and partly by angry menaces, to induce him to com-
Acadians, in the presence of Constantius. However, the Acadians prevailed against him in the council of Constanti-

nople, A.D. 362, and procured his d, position; nevertheless he kept possession of his see, and was acknowledged as bish-

op by the orthodox prelates. Baill is supposed to have di-

ded either at the end of Julian's reign, or the beginning of

that of Valens. Cave, H. E. tom. i. p. 216. Lardner's

Basil, Order of St. in Ecclesiastical History, is the most

ancient of all the religious orders. It takes its name from

St. Basil, bishop of Caesarea, in Cappadocia, about the mid-

dle of the fourth century; who is supposed to have been

the author of the rules offered by this order, though

some dispute it. The order of St. Basil was anciently very

famous in the East, and still continues in Greece. The

habit of the monks is black, and plain, consisting of a long

cassock, and a great gown with large sleeves; on their head,

they wear a hood, which reaches to the shoulders; they

wear no breeches; sleep without sheets, on straw; eat no sub-

ject; and till the ground with their own hands. The

historians of this order inform us, that it has produced

1365 bishops, and bestowed, or acknowledged as saints,

5210 abbots, 11,885 martyrs, and an infinite number of confes-

sors and virgins. They likewise place among the religious

of this order of St. Basil, 15 popes, several cardinals, and many

patricians, archbishops, and bishops. It likewise beak

of several emperors and empresses, kings and queens, princes

and princes, who have embraced the rule of St. Basil.

This order was introduced in the West in 1557, and was

reformed in 1579 by pope Gregory XIII., who united the

religions of this order in Italy, Spain, and Sicily, into one

congregation; of which the monastery of St. Saviour, at

Melfina, is the chief, and enjoys pre-eminence over the

rest. Each community has its particular rule. Besides

the rule of St. Basil, which is very general, and prefers little

more than the common duties of a Christian life.

Basil, Right, or Balle, in Geography, one of the new

cantons of Switzerland, which joined the Helvetic confed-

eracy in 1501. It is bounded on the west and south by

the canton of Solothurn, on the east by the canton of

Bavaria, on the north-east by the territory of the

Rhinefels, and on the north-west by Aarival, and on the west by the bishopric of Balle. Its

extent is about 160 square miles, and its population is

estimated at 40,000 persons. The lower parts of this can-

ton are fertile in corn and wine, and also for pasture; but

the mountains are extremely barren. It has many medi-

cal springs and baths, and the air is temperate and balmy.

The religion of this canton is the reformed, or Protestant.

As to its ancient government, the bishops of Baill once

possessed the sovereignty over the city and canton; but when

they quitted this town in 1501, and retired, fist to Fribur,

and afterwards established their residence at Po-

teruia, they lost the inconsiderable authority and few pre-

rogatives that belonged to them. Upon the introduction of

the reformation in 1535, the constitution was in some mea-

sures changed, and the power of the arbitrariness limited.

Before the late revolution, the government was aristocratic,

inclining towards a democracy. The supreme legislative

power resided in the great and little councils, consisting of

about 350 members, and the authority of these two councils

was without control; they enacted laws, declared war and

peace, contracted alliances, and imposed taxes; they desig-
ned the several magistrates, appointed their own members, nomi-
nated to all employments, and conferred the right of bugg-

chirp. The general administration of government was com-
mittied, by the great council, to the femage or little council;

that is, to a part of its own body. This femage, composed of

sixty members, together with the four chiefs of the re-

public, two burgomasters, and two grand tribunals, was di-

vided into two bodies, which acted by rotation; the acting

division continued in office one year, decided finally in all

matters of importance, with the advice of the police, and exer-
cised general powers subordinate to the foreigner council.

The collective body of citizens assembling only once a year,

when the magistrates publicly took an oath to maintain the

constitution, and to preserve the liberties and immunities of

the people inviolate. The recitoval oath of obedience to the

laws was administered to the citizens in their respective

tribes. But, notwithstanding the humblest prerogatives of

the great council, the meanest citizen was legally capable of

being admitted into that body, and, by the singular method of

election, might possibly be chosen: for the vacancies in

the two councils were fupplied from all ranks of citizens,

the members of the universi only excepted. These citizens

were divided into eighteen tribes, fifteen of which belonged to

the larger towns, and three to the smaller; each of the

fifteen tribes returned four members to the femage, and each

of the eighteen to the great council. As these
councils were formerly determined by a plurality of voices, the

richest person was always almost certain of being chosen;

to prevent which, a regulation, called a "ternaire," was

established; that is, three candidates were nominated, and

from these the successor was appointed by lot. In 1740,
a sort was passed, by which the "ternaire" was changed into a "senator," by which six candidates were put in nom-

ination, and drew lots for the place; six tickets, contain-
in the names of the respective candidates, and separately

placed in silver bags, were put into one bag, and the same

number of tickets, five being blanks, and one marked with

the vacant employment, were put into another bag; the

regime burgomaster and the great tribune, appointed to be

the drawe of this official lottery, both at the same in-

s tant took a ticket from each bag, and the candidate whose

name came out with the ticket on which the employment

was written, obtained the pill—but it is now necessary to

pursue the detail. In 1758, the Helvetic confed-
BA S

vol. i. What other changes await the Swiss cantons, time
must develop. See SWITZERLAND.

BA S, or BASL, the capital of the canton of the same
name, is the largest, and seems formerly to have been one
of the most populous towns in Switzerland. Its extent is capable
of containing above 100,000 inhabitants, and it is said to have
220 streets, and five market-places or squares; whereas it
can now scarcely number more than 14,000. Among the
causes which have contributed to its decay, Mr. Coxe
mentions the jealousy of the citizen with regard to the
bourgeois, which they felt to design to confer upon for-
reigners; and, on this account, it is not surprising that great
efforts are made to balance that gradual waste of people which takes place
in great cities, from an influx of strangers, who are not permitted
to carry on commerce, or to follow any trade. The
late law that allows the freedom of the town and the right
of burghership to be conferred upon strangers, is clugged
with so many restrictions, that it by no means answers the
purpose for which it was intended.

Bale is beautifully situated on the banks of the Rhine,
near the point where the river, which is here broad,
deep, and rapid, after flowing for some way from east
west, turns suddenly to the north. It consists of two
towns, joined together by a long bridge; the large
town lying on the side of Switzerland, and the small
town on the opposite bank of the river. Its environs are
very beautiful, consisting of a fine level tract of fields and
meadow. It was anciently called Basilia, as we learn from
Ammianus Marcellinus; and in the middle ages, Basilia:
and it appears in history, soon after the reign of Charle-
smagne; having succeeded Augst, or the Augglia Raurac-
corum. Bale is very favourably situated for commerce;
and of this advantage the inhabitants have availed them-
selves, by establishing a great variety of manufactures,
particularly of ribbons and cottons; and by the extensive
trade that is carried on by the principal merchants. The
cathedral is an elegant Gothic building, and contains the
marble tomb of the famous Lefanfus, who chose this city as
his favourite place of residence, and published from hence
the greatest part of his valuable works. Bale has, besides
the cathedral, six parochial churches, and several other pub-
lic buildings such as a public granary and an arsenal, a
town-house, and a lately palace belonging to the margrave
of Baden-Durlach, a chamber of curiosities, several hospit-
als, &c. In the town-house is an exquisite piece of the
sufferings of Christ, by Holbein, who was a native of this
place; and a statue of Munatius Plancus, the Roman gen-
eral, who founded Augglia Rauracorum. In the arsenal is
shewn the armour in which Charles the Bold lost his life,
with the furniture of his horse, and the kettledrums and
trumpets of his army. On the fleir-cafe of the council-
house is a picture of the last judgment, in which, though
painted before the reformation, popes, cardinals, monks, and
priests, are represented in the torments of hell. Upon a
wall that includes the burial-ground of the church of the Pro-
tellants in the suburb of St. John, is painted, in oil colours,
the "dance of death," erroneously attributed to Holbein,
as it was painted before he was born, in which the king of terrors
is represented as mixing with all ranks and ages, and com-
plimenting them in German verses on their arrival at the grave.
From this ancient painting, it is thought, that Holbein
took the first hint towards composing his famous drawings on the
"dance of death." Prints were taken from some of
these drawings by Holir, which are now very scarce. The
university of Basle, founded by pope Pius II. in 1439, or
1460, was formerly eminent in the literary history of Eu-
rope. It was honour'd by the celebrated names of Occel-
padus, Amerbach, the three Baudin, Gryneus, Buxtorf,
Vol. III.

Wetstein, Belin, the Bernonillis, and Euler; and it still
boasts of the members who are ornaments to their native
town by their learning and talents. The public library con-
tains a small collection of books, remarkable for its rare
and valuable editions, particularly of those printed in the
15th century. Besides books, this library contains some
valuable MSS. In a suite of rooms belonging to it, are
a cabinet of petrifications, some ancient medals and gems, a
few antiquities found at Augst, a large number of prints,
and some fine drawings and paintings, confiding chiefly
of originals by Holbein, most of which are in the highest
pre-
formation. Basle is famous for the excellence of its police,
and the strictness of its municipal laws. Although the use
of coaches is not prohibited, yet no citizen or inhabitant
is allowed to have a servant behind his carriage. No person,
it is said, without the city, must wear lace of gold or silver;
and all young women are prohibited from wearing furs.
By such regulations, a distinguishing simplicity of manners
prevails even in the richest families. It was formerly a sin-
gularity belonging to this town, that all its clocks were an
hour faster than the real time, which, according to some,
was introduced during the council of Basle, in order to en-
mence the cards and bishops in due season for the dispatch
of business; others say, that they were put forward, in
order to defeat a conspiracy, by one of the burgomasters,
who had notice of the design; by which the conspirators,
thinking that they had milled the time and were too late,
were induced to retire; others say, that the sin-dial on the
cathedral, which regulates the clocks, declines from east
from the east, and this circumstance, according to Beloni-
ni, occasions a variation from the true time of about 45 minutes.
The inhabitants have long tenaciously maintained this an-
cient custom, and refilled every change; till in the late new
order of things, a revolutionary change has taken place with
regard to the clocks as well as the government, and they
have been altered to the true time. Basle was formerly the
see of a bishop; but though there is one that now bears the
title, he lives at Porrenz near Alvaize, and has no jurisdic-
tion in this city.

The famous council of Basle began its fittings in
1431, continued its deliberations, and proceeded in en-
acting laws and publishing edicts, until the year 1443,
notwithstanding the efforts of pope Eugenius, who had
been deposed from the popacy of the council in 1439,
and his adherents, to put a stop to their proceedings.
And though in that year the members of the council retired
to their respective places of abode, yet they declared pub-
licly that the council was not dissolved, but would resume
its deliberations at Basle, Lyons, or Laufenbe, as soon as a
proper opportunity occurred. Accordingly, in the year
1449, when Felix V. resigned the papal chair, the fathers
of the council of Basle assembled at Laufenbe, ratified his
abdication, and, by a solemn decree, ordered the univer-
sal church to submit to the jurisdiction of Nicholas
as their lawful pontiff. Nicholas set the seal of his approba-
tion and authority to the acts and decrees of the council
of Basle. The two grand points that were propounded to the
deliberation of the famous council of Basle, were the union
of the Greek and Latin churches, and the reformation of
the church universal, both in its head and in its members,
according to the resolution that had been taken at the coun-
icil of Conlance. In 1455, this council publicly abolished
the "annates;" and in 1456, a confession of faith was read,
which every pontiff was to subscribe on the day of his elec-
tion; the number of cardinals was reduced to twenty-four;
and the papal impositions called "expectatives," "refer-
vations," and "provisions," were annulled. Mait. Eccl.
Hist. vol. iii. p. 420, &c. N. lat. 47° 35'. E. long. 7° 29' 30".

5
BASIL, or Basle, being a principality of Germany, in the circle of the Upper Rhine, may be divided under two general divisions: the first lies to the south of Pierre Pertus, and forms a part of Switzerland; the second, to the north of the same boundary, includes that district which is properly situated within the German empire. The sovereign, that is, the bishop of Basle, or, as he is called by the Protists, the prince of Preterru, whose principal residence is Preterru, the capital of his dominions, was formerly chosen by the chapter of eighteen canons, resident at Arlesheim, and confirmed by the pope. He was a prince of the German emperors, and did homage to the emperor for that part of his territory which lies in the circle of the Upper Rhine. He was always considered as an ally of the Swifs by his union with the Catholic cantons, first formed in 1579, and renewed at different intervals, particularly in 1671 and 1697, and by being included in the treaty which those cantons contracted with France in 1715; but as he was not comprised among the allies of the Swifs, in the league between the thirteen cantons and Louis the XVIth, in 1777, he was not deemed a member of the Helvetian confederacy. The first particular alliance with France was concluded in 1739, between the bishop and Louis the XVIth, and was renewed in 1783. The population of that part of the bishopric of Basle that was ailed to the cantons amounted to 24,600. The form of government was a limited sovereignty, the bishop being bound, on all important occasions, to consult his chapter; and his prerogative being confined, by a great immunities enjoyed by his suffragans in general, and particularly by those of the reformed communion. He nominated all employments both civil and military, and appointed the bailiffs or governors; judicial justice was administered in his name, and his the power of pardoning. In civil proceedings, he received an appeal from the inferior courts; but in his German dominions, when the cause exceeded the value of a duplulum, it might be carried to the chambers of Wetzlar or Vienna. The subjects of the bishop are partly Protists and partly Catholics: the Protists inhabit the greatest part of the valley of Munster, and the whole district to the south of Pierre Pertus, and are about 15,000; the Catholics amount to 35,600. The French and German languages are both spoken in the bishop's dominions. The whole bishopric of Basle is now annexed to France. In 1793, their troops over-ran the country of Preterru, on the German part, under the pretence of delivering the natives from slavery, and took possession of the famous falls of Pierre Pertus. This district was ceded to France by the treaty of Campo Formio, and is formed into the department of Mont Terrible. In 1798, the Helvetian part of the territory was taken possession of, in the name of the republic, by general St. Cyr, under a declaration that France succeeded to the property, dominions, rights, and prerogatives of the bishop. This district was also annexed to the department of Mont Terrible. The bishopric of Basle is a fertile country, and many forges are employed in the manufactures of iron and steel. Basle, among Joiners, denotes the angle to which the edge of an iron tool is ground. To work on soft wood, they usually make their bāl 2 degrees; for hard wood 18°: it being observed that the more acute or thin the bāl is, the better and faster it cuts; and the more obtuse, the slower and fitter it is for service.

BASILIAN, or Bassillian, in Geography, one of the Philippine islands; 12 leagues in circumference, very fertile, especially in fruit and rice; 6 leagues S. W. of Mindanao. N. lat. 5° 51'; E. long. 121° 30'.

BASILARE Os, in Anatomy, a barbarous denomination given to the os pharnsonis, on account of its being situated at the bottom or basis of the skull; or because a great part of the brain rolls upon it, as on its basis.

BASILARIS Artexia. See Artery.

BASILE, St. in Geography, a town of Italy, in the kingdom of Naples, and province of Orantra, at 18 miles east of Matera.

BASILE, St. is also a town of the kingdom of Naples, in the province of Babblicata; 11 miles E. of Turin.

BASILEUS, Basileus, a title assumed by the emperors of Constantinople, exclusive of all other princes; to whom they give the title rex, king. The same quality was afterwards given by them to the kings of Burgundy, and to Charles the Caesars; from the successors of which last they endeavored to wrest it back again.

The title basileus has been since assumed by other kings, particularly the kings of England; "Ego Edgarus rex Anglorum basileus confirmavi."

Hence also the queen of England was intituled basileia, and Basilius.

BASILEUS, in Orithgology, a name by which many of the ancient authors called the Regus Orithi, the Alcove, the Motacilla Regulus of the Latin Fylen, or the golden-crowned warbler.

BASILI, in Geography, a river of European Turkey, which runs into the gulf of Colokitia, 4 miles N. N. E. of Colokitia.

BASILI, St. a town of European Turkey, in the Morea; 8 miles S. of Corinth.

BASILIA, a town of Poland, in the palatinate of Volhynia; 52 miles W. S. W. of Constatinop.

BASILIA, or Basilico, a fortified town north of Corinth, situated upon the coast of the gulf of Lepanto.

BASILLANS. See B. Gomili.

BASILIC, basilica, is used in Eccl.ical Writers, for a church. In which sense this name frequently occurs in St. Ambrose, St. Aurelia, St. Jerome, Sidonius Apollinaris, and other writers of the fourth and fifth centuries.

M. Perani says, that basilicas differed from temples, in that the columns of temples were without side, and those of basilicas within.

Some will have the ancient churches to have been called basilicas because generally built in the fashion of the Roman halls called by that name; others, because divers churches were formed of these halls. Some have supposed that, on the conversion of Constantinople, many of the ancient basilicas were given to the church, and turned to another use, viz. for Christian assemblies to meet in; and they refer to this usage in Aulicostus, where, speaking to the emperor Gratian, he tells him, the basilica, which he supposed were wont to be filled with men of_bufines, were now throned with votaries praying for his safety; by which it is apprehended he meant, that the Roman halls or courts were turned into Christian churches, and hence it has been conceived, that the name basilica came to be a general name for churches in later ages. See Basilica.

Basilic is chiefly applied, in modern times, to churches of royal foundation, as those of St. John de Lateran, and St. Peter of the Vatican, at Rome, founded by the emperor Constantine.

Basilic appears also to have been given, in later ages, to churchs before consecration.

Basilics were also little chapels built by the ancient Franki over the tombs of their great men; so called, as resembling the figure of the sacred basilica or churches.

Perons of inferior condition had only tumubs, or porticus, erected over them. By an article in the Salic law, he that
that robbed a tumba or piiculcis, was to befixedc using foldi; but he that robbed a basilica, thirty foldi.

BASILICA, or BASILICUS, in Anatomy, the name of a vein, arising from the axillary branch, and running the whole length of the arm. The basilica is one of the veins opened in bleeding in the arm. See Vein.

BASILICA, in Architecture. This word, which has successively received very different acceptations, is derived from Basileus, king, and signifies: it means, therefore, etymologically, royal house. Perhaps the halls of justice acquired this name in early antiquity, when the judging of the people might be regarded as the peculiar royal prerogative; and it was natural that they should retain this appellation, when justice was no longer administered by kings. Among the public edifices composed of a single building, the basilica appears to have been one of the largest. It was, among the Romans, an ample hall adjoining to the Forum, in which the magistrates judged under cover; which distinguished it from the fora, where they held their sittings in the open air. Here the tribunes and centumvirs administered justice, and the juridiconstiti and legalis in the pay of the republic, advised those who came to consult them. Young actors declined in separate apartments, and the porticos were occupied by merchants and traders. Thus these edifices were at the same time applied to the purposes of commerce and judicature.

It is to be lamented that the antique basilicas have to entirely perished, that the construction and disposition of them are involved in great doubt and obscurity. Vitruvius, the only ancient architect whose writings have descended to us, gives the following description of the Roman basilica.

The basilica should be adjoined to the forum on the west side, that the merchants may confer together without being interrupted by the weather. The breadth is not made less than the third, nor more than half the length; unless the nature of the place or those parts of the proportion, and obliges the symmetry to be different. But if the basilica is too much length, chalcis are made at the ends, as they are in the basilicas of Julia Aquianna. The columns of the basilicas are made as high as the portico is broad. The portico is the third part of the space in the middle; the upper columns are a fourth part less than the lower. The plausum, which is between the upper columns, should also be made a fourth part less than the same columns, those who walk in the floor above may not be seen by the merchants below. The epistyle, xiphosorus, and corona, are proportioned to the columns, in the manner explained in the third book.

The basilica, however, which Vitruvius erected at the colony of Julia of Fausum, did not conform to the foregoing precepts. It is thus described: 'A middle tetradoch (aile or nave) is 120 feet long, and 60 feet broad; the surrounding portico between the walls and columns is 20 feet broad. The columns, continued the whole height of the building, are 50 feet, including the capitals, and 5 feet in diameter; having behind them pilasters 20 feet high, which sustain the beams that bear the floor of the upper porticos. Above these pilasters are others 18 feet high, which support the ceiling of the upper porticos, which is laid lower than the roof of the tetradoch, the space between being left open in the intercolumniations for light. The columns in the breadth of the tetradoch are four including those of the angles; and in the length, of the side rest the forum, including the same angles, eight. On the other side there are but five, the two in the middle being omitted; that they may not obstruct the view of the pronaos of the temple of Augustus, which is situated in the middle of the side wall of the basilica.'

The tribunal in this building is in the figure of a hemice, extending in front 40 feet, and receding in the centre of the curvature 15 feet; so that those who attend the magistrate obstruct not the merchants in the basilica.'

From the preceding descriptions it would appear, that the ancient basilicas consisted of a great nave in the middle, surrounded with but one range of porticos; and it is thus that it has been represented in the designs of all who have restored it from the words of Vitruvius. However, the fragments of the plan of Rome taken under Septimius Severus, which still exist, shew a part of the basilica Ambelina; and in this authentic record we find two rows of columns on each side, which, supposing an exterior wall, would give two ranges of porticos. But this valuable relic gives reason to doubt, whether the basilicas were surrounded with walls, or whether their porticoes, open on every side, communicated with the public places. The description of Vitruvius explains nothing in this particular; but it may be inferred from what he recommends relative to the warmth of the exposure, that they were not enclosed.

Supposing the entrance of the basilica to be at one end, the other was terminated by a hemicycle, in which was placed the tribunal; this circular end answers to the abridgment of the Christian basilica. The chalcis mentioned by Vitruvius have given rise to various conjectures, which it would be useless to detail, as we have no data from which any other inference can be drawn, than that they were some kind of apartments, separated by a partition, at the ends of basilicas.

Before the excavations made at Otricoli, and the discoveries which were the result, we had only conjectures on the form and nature of the ancient basilicas; uncertain vestiges were all that remained of those of Rome, and the situation of such the famous basilicas, Ambelina and Fulvia, was sought in vain at Praeneste. The monument of Otricoli, therefore, ought to be very precious if we find in it a true basilica, of which the reader will be enabled to judge from the following description.

To discern the essential character of a basilica, it will be useful previously to consider the difference between it and a temple. The original form of a temple is an oblong cela or body, surrounded with porticos, and even where the lateral porticoes were suppressed, they were never deprived of a pronaos or portico in front. In short, in the basilica the porticoes were internal and external in the temple. Now the edifice of Otricoli has no exterior colonnade, neither pronaos nor peristyle. It is a square building, surrounded with a simple wall. In the middle the entrance is by a rustic opening, without any vellum of decoration. The interior contains a great hall, divided by porticoes into three naves or aisles. The portico immediately opposite the entrance is composed of three arches, eight Corinthian columns form the remaining three porticoes; the further end of the building is occupied by a hemicycle or tribunal, on each side of which is a small apartment. The tribunal is ascended by several steps, and round the interior of the edifice is continued a pedestal, on which were statues which have been transported to the Museo Vaticanum. The ceiling was probably of wood, as there are no remains of a vault. No vellums lead even to suppus that in the middle there might be a base for a statue, or any thing that indicates a temple.

This monument is certainly deficient in many of the characteristics of a basilica; its plan is a exact square instead of an oblong, and the upper galleries are wanting. However, considering to what variations these edifices were subject, according to the riches, the size of towns, and the diversities of situation; and how much Vitruvius, the author
of the precepts which should fix our ideas on this subject, has departed from his own rules in the construction of his basilica. It must perhaps be impossible not to recognize, in the edifices of Ostrogoth, an example of the ancient basilica.

But we cannot quit this division of the subject without mentioning a monument, interceding at any rate from the singularity of its architecture, and still more so if it preserve to us the form of the Grecian basilica. This edifice, one of the antiquities of Paestum, is in length the double of its breadth; it is formed by ranges of Doric columns, to the number of nine in each front and eighteen on each wing, including the angles. On a line with the central column of each front a range of columns is continued through, dividing the building into two parts: at the foot of these columns the pavement is elevated and adorned with mosaic. These interior columns supported the roof, which was probably a terrace. The uneven number of columns in the fronts, and the narrowness of their intercolumniations compared with those of the wings, prove sufficiently that the principal entrances must have been at the sides; and this circumstance, together with the absence of any exterior wall to inclose a cela, shews that this edifice could not have been a pure temple. But to the purposes of a basilica it seems very well adapted; open on every side, it admitted an easy access, while the elevation or bank in the middle, would afford a tribunal suited to the singularity of the age.

The Ecclesiastical Basilica. It is not probable that the ancient basilicas were ever converted into Christian churches; in that case, we should still be in possession of some of these monuments of antiquity. The most ancient basilicas of the Christians, those which date from the first centuries of the public exercise of our religion, were built expressly for their use; and the details of their architecture, announce but too clearly the time of their construction. But these new temples resembled so much the antique basilicas, that they retained their name: and indeed if we examine the buildings of antiquity, we shall find no other so well calculated for the purposes of our religion. These edifices, at once simple in plan and magnificent in decoration, were of a form and disposition the most advantageous that can be imagined for large halls, and their construction combined solidity with economy. Their solidity is proved by the duration of fourteen centuries of some of these buildings; and their economy consists in the lights of the points of support, and in that of the covering which was only of carpentry. In most of the basilicas, the walls and the points of support only occupy one tenth of the total space; which, in buildings vaulted and supported with arcades, like many modern churches, take up at least twice that superfi senses, and require besides materials and modes of construction which quadruple the expense.

It is to Constantine, that the first Christian churches known by the name of basilicas are to be referred. This prince signalized his zeal by the erection of monuments which announced the triumph of the religion which he had embraced. He gave his own palace on the Cecilian mount to construct on its site a church which is recognized for the most ancient Christian basilica. A modern building has so much masked and disfigured the ancient, that only the situation and plan of this monument can be discovered.

Soon after, he erected the basilica of St. Peter of the Vatican. This magnificent edifice was constructed about the year 324 upon the site of the circus of Nero and the temple of Apollo and Mars, which were delineated for that purpose. It was divided internally into five aisles from east to west, which terminated at the end in another aisle from north to south, in the centre of which was a large niche or tribunal, giving the whole the form of a cross. The larger aisle was inclosed by forty-eight columns of precious marble, and the lateral aisles had likewise forty-eight columns of smaller dimensions; two columns were placed in each wing of the terminating aisle. The whole was covered with a flat ceiling, composed of many blocks, which were carved with gilt metal and Corinthian brafs taken from the temples of Romulus and Jupiter Capitolinus. A hundred smaller columns ornamented the fritures and chapels. The walls were covered with paintings of religious subjects, and the tribunal was enriched with elaborate mosaics. An incredible number of lamps illuminated this temple; in the greater solemnities 2,400 were reckoned, of which one enormous candlabrum contained 1,560. The tombs of pontiffs, kings, cardinals, and princes, were reared against the walls or inlaid in the ample porticoes.

This superb temple was respected by Alaric and Totila, and remained unjured in the various fortunes of Rome during the lapse of twelve centuries; but crumbling with age, it was at last pulled down by Julius II. and upon its site was arisen the famous basilica, the pride of modern Rome.

The third great basilica built by Constantine, that of St. Paul on the road to Olbia, still exists. The interior of this building refembles precisely that of St. Peter which has just been described. Of the forty columns including the great aisle, twenty-four are supposed to have been taken from the mausoleum of Hadrian; they are Corinthian, about three feet diameter, fluted their whole length, and cabled to one third; the columns are of blue and white marble, and antiquity presents nothing in this kind more precious for the materials and the workmanship. But these beautiful remains seem only to be placed there to the disgrace of the relic of the construction, which is of the age of Constantine and Theodorus, and which most strikingly exemplifies the rapid decline of the arts.

The churches we have hitherto referred bear a very complete resemblance to the antique basilica in plan and proportion. The only remarkable difference is, that the superior galleries are suppressed, in the place of which a wall is raised upon the columns of the great aisle, which is pierced with windows, and supports the roof.

The church of St. Agnese out of the walls, though not one of the seven churches of Rome which retain the title, is however a perfect imitation of the antique basilica. This resemblance is so complete, that without the testimony of writers who inform us that it was built by Constantine at the request of Constanina his sister or daughter, and without the details of its architecture which forbid us to date it higher, it might be taken rather for an ancient tribunal of justice than a modern church. It forms an oblong internally, three sides of which are surrounded with columns forming the porticoes; the fourth side opposite the entrance is re- ceived in a semicircle; this is the tribunal. The first order of columns carries a second, forming an upper gallery; above which begins the ceiling of the edifice. The shortening of the columns, recommended by Vitruvius, is observed in the upper order.

We have hitherto referred in the Christian basilicas but small variations from the antique construction; they were still simple quadrilateral halls divided into three or five aisles, the numerous columns of which supported the flat ceiling; but the cross form, the emblem of Christianity, which began to be adopted in these buildings, operated the most essential changes in their shape. The interjection of the crossing aisles produced a centre, which it was natural to enlarge and make principal in the composition; and the invention of domes.

6
B A S I L I C A.

domes supported onpendentives enabled the archi tects to give size and dignity to the centre, without interrupting the vista of the aisles. The church of St. Sophia at Constantino ple was the first example of this form.

The fact of the Roman empire being transferred to Con stantinople, it is natural to suppose that the disposition of the ancient St. Peter's of Rome, esteemed at that time the most magnificent church in the world, was imitated in that which Constantine erected for his new capital under the name of St. Sophia. This last did not exist long: Constantius, the son of Constantine, rased a new one which experienced many disasters. Destroyed in part, and rebuilt under the reign of Arcadius, it was burnt under Honorius, and re-established by Theodosius the younger; but a furious fire having arisen in the church, it was reduced to ashes. This emperor having appealed the tumults, and willing to immortalize his name by the edifice he was about to erect, embellished from various parts the most famous architects. Anthemius of Tralles and Isidore of Miletus were chosen; and as they had the boldness to attempt a novel construction, they experienced many difficulties and dissatisfactions; but at last they had the glory of finishing their design.

The plan of this basilica is a square of about 250 feet. The interior forms a Greek cross, that is, a cross with equal arms; the aisles are terminated at two ends by semicircles, and at the other two by square recesses, in which are placed two ranges of tribunals. The aisles are vaulted, and the centre, where they intersect, forms a large square, upon which is raised the dome, of about 110 feet diameter. The dome, therefore, is supported upon the four arches of the naves and the pendentives or spirals which connect the square plan of the centre with the circle of the dome. The general effect of the interior is grand; but whatever praises the bold invention of this immense dome merit, it must be confessed that there are times in which princes, however great and liberal, can only produce imperfect monuments, of which this edifice is a striking example. All the details of its architecture are defective and barbarous.

However, from the communication established between Greece and Italy, at the revival of letters, this basilica, the last as well as the most magnificent of the lower empire, was that which influenced most the form and architecture of the new temples. The Venetians, in the tenth century, copied with success the left parts of the disposition of St. Sophia in the church of St. Mark. This is the first in Italy which was constructed with a dome supported upon pendentives; and it is also this which first gave the idea, which has been imitated in St. Peter's, at Rome, in the Vatican, of accompanying the great dome of a church with smaller and lower domes to give it a pyramidal effect.

From this time to the erection of the basilica of St. Peter's we find the churches approach more or less, to the form of the ancient basilicas or the new construction. The church of Santa Maria del Fiore of Florence, from the magnitude of its dome and the skill which Brunelleschi displayed in its construction, acquired a celebrity which made the system of domes prevail; and this system was finally established in the noble basilicas of the Vatican, which has become the type and example of later ones. The form of the antique basilica was entirely lost, and the name, which has been retained, is the only remain of their ancient resemblance.

In the pontificate of Julius II, the beginning of the 16th century, the basilica of St. Peter's was begun from the design of Bramante. This great man formed the idea of suspending in the centre of the building a circular temple as large as the pantheon, or, as he expressed it, to raise the pantheon on the temple of peace; and, in fact, we find great resemblance in size and disposition between these two edifices and the project of Bramante. He was succeeded in his office by San Gallo, who almost entirely lost sight of the original plan; but Michael Angelo, to whom at his death the undertaking was committed, centered the discordant parts, and contracted the whole into the form of the Greek cross. Michael Angelo died in 1564, while he was engaged in erecting the dome; but he left plans and models which were strictly adhered to by his successors, Vignola, J. de la Porte, and Fontana, who terminated the dome. The building was carried on under many succeeding pontiffs; and at last, by lengthening the longitudinal naves, it acquired the form of the Latin cross; in that particular, approaching to the original design of Bramante.

The general form of this edifice externally is an oblong, with circular projections in three of the sides; the plan of the interior consists of a Latin cross, the intercolumniation of the arms of which is enlarged and formed into an octagon; the head of the long aisles and the ends of the cross aisles are terminated in hemicycles; and the great naves are accompanied with lateral aisles and with several inclosed chapels. The octagon centre supports a circular wall enriched with pilasters and pierced with windows, above which rises the magnificent dome.

Thus we have traced the progress of the basilica from the quadrilateral hall of the ancients, with its single roof and flat ceiling supported on ranges of columns, to the cross-shaped plan, central dome, and vaulted aisles supported on massive piers of the modern cathedral. It only remains to treat of the

Modern Basilicas. We give this name with Palladio to the civil edifices which are found in many Italian cities, and the designation of which is entirely familiar to the antique basilicas.

In imitation of the ancients, says this celebrated architect, the cities of Italy construct public halls which may rightly be called basilicas as they form part of the habitation of the supreme magistrate, and in them the judges administer justice. The basilicas of our time (he continues) differ in this from the ancient; that those were level with the ground, while ours are raised upon arches in which are shops for various arts and the merchandise of the city. There the prisons are also placed, and other buildings belonging to public buffets. Another difference is that the modern basilicas have the porticoes on the outside, while in the ancient they were only in the interior. Of these halls there is a very noble one at Padua; and another at Brescia, remarkable for its size and ornament.

But the most celebrated is that of Vicenza; the exterior part of which was built by Palladio, and the whole so much altered that it may pass for his work. The body of the building is of much greater antiquity, though the date of it is unknown.

Time and various accidents had reduced this edifice to such a state of decay, that it was necessary to think seriously of preserving its total ruin: for this purpose the most eminent architects were consulted, and the design of Palladio was approved. He removed the ancient loggias, and substituted new porticos of a very beautiful invention. These form two galleries in height, the lower order of which is ornamented with Doric engaged columns, at very wide intervals, to answer to the internal pillars of the old building; the space between each column is occupied by an arch resting on two small columns of the same order, and a pilaster at each side against the large columns, which leaves a space between it and the small columns of two diameters. The upper portico of Ionic columns is disposed in the same manner, and a balustrade is placed in the archways. The

embellishment
entablature of the large orders is profiled over each column.

This edifice is about 150 feet long and 60 feet broad: the hall is raised above the ground 20 feet; it is formed by vaults supported on piers, and the whole is covered with a wooden dome. See Plate II. of Architecture, the Roman basilica, from the description of Vitruvius. Plate III, the basilica at Paulus, Plate IV, the plan of the old basilica of St. Peter, founded by Constantine. Plate V, plan of the modern St. Peter's of the Vatican. Vitruvius Arch. de A. Palladio. "*Collagiata Pianta del Vaticano," Excve. Mech.”

**BASILICAS.** Basilica, a collection of the Roman laws, translated into Greek by order of the emperors Basil and Leo, and which were of force in the eastern empire till its disjunction.

The basilica comprehends the institutes, digests, code, and novels, and some edicts of Julian and other emperors. The collection consisted of fifty books, for which reason it was called *Suarum.* It is supposed to have been the work of the emperor Leo the Philosopher, who dedicated it to his father Basilios Mecido, who first began it in 597, and carried the work to forty books. It was published by Leo, with the addition of twenty books more, in 599; and thirty years after, corrected and improved by his son Constantius Porphyrogenitus. Six books of the basilica were translated into Latin in 1557, by Gentianus Heraeus. Of these fifty books, there are now remaining only forty-one; an edition of which, with a Latin version, was published by Charles Ambro Fabrotta, at Paris, in 1647, in seven folios; the other nineteen are in some measure supplied by Fabrotta, from the "Synopsia Basilicorum," &c. Four other books have been since discovered, and are inserted in G. R. M. M. H. M. L. "Novae Theaurae Juris Civ. et Canon." Tom. V. Of the whole work, the sixty books, J. Leunclavius has printed at Basle, in 1575, an edifice or synagoga. On the subject of the basilica, Fabricius (Bib. Græc. t. viii. p. 426—434) Heracleous (Hist. Juris Romani, p. 266—269), and Giovanni (Italia Civi. di Napoli, tom. i. p. 450—453) as historical civilians, may be usefully consulted.

**BASILICATA,** in Geography, a province of the kingdom of Naples, bounded on the north by the Captains, and the Terra di Bar, on the east by the gulf of Tarento, on the south by Principato Citra and Calabria Citra, and on the west by Principato Ultra. Its extent is about 1,600,047 morgges, 5 morgges making 4 English acres; and the number of its inhabitants about 352,632. Its rivers are Brindisi, Bistento, Salandra, Asti, and Sina; its lakes are Lygongro and Olmo; its mountains are the most part branches of the Apennines; and its principal places are Accera, Meli, Monte-Pelato, Tricario, Potenza, Anglona, Venola, and Muro; its ruined cities are Metapontum and Heraclea. This province produces corn, wine, oil, flax, silk, cotton, honey, and wax.

**BASILICI,** in Greek, the Greek Empire, was a denomination given to the prince's mandatories, or those who carried his orders and commands.

**BASILICON,** or **BASILICUM,** in Pharmacy, is the pompous denomination formerly given to an officinal unguent or plaster, much refuging and superadded by the *Seuulturn Refina Flauze.*

**BASILICUS,** or **BASILICA,** in Astronomy, is the name of a fixed star of the first magnitude in the constellation Leo; called also regularus, and cor leonis.

**BASILICA Sinus,** in Ancient Geography, the gulf of Melisso, a gulf of Asia Minor, in Caria, which it separates from Ionia.
Irenæus's account, Jesus appeared as man, but was not so in reality, and wrought many miracles: however, he was not crucified: the Jews, having, through misfortune, crucified Simon the Cyrenian in his stead. Many of the ancients have, upon the authority of Irenæus, accused Basilides of denying the reality of Christ's body, and of maintaining that Simon was crucified in his stead. But this accusation, as far as it refers to Basilides himself, is groundless; for he seems to have considered the divine Saviour, as compounded of the man Jesus, and Christ the Son of God. To this purpose Beanzibore says, that though Basilides did not believe the incarnation, or hypothetical union of the Son of God with flesh, yet he never denied that Jesus was a real person, in whom the Understanding, or Son of God, displayed his power, when he filled with his gifts and illuminations, and invested with extraordinary influence. With regard to the ridiculous story of Simon transformed into Jesus, and crucified in his stead, it represents him as a fable which Irenæus derived from some unknown source. As Basilides believed the death of Jesus, who was a real and most excellent man, in whom the first-begotten of the Father choe to dwell, though not of the Son of God, he probably believed his resurrec tion: that is, that his soul ascended to heaven, and the body was left to lie in the grave, or was disintegrated into the air, and among the elements of which it was composed.

As the ancient Catholic writers do not particularly say that Basilides denied the resurrection of Jesus, though they ascribe him and his followers the denial of the resurrection of the body; it is not unlikely that he admitted the resurrection of the advancement and glorification of the soul of Jesus. Basilides believed the fact of the baptism of Jesus; and his followers, as Clement informs us, celebrated the day of his baptism as a festival, which was the 15th day of the Egyptian month Tybi, corresponding to the 9th or 10th of Janu ary, in the 15th year of Tiberius; and they spent the whole preceding night in reading, and probably in prayers. Some persons have supposed that Basilides denied the necessity or reasonableness of our suffering martyrdom for Jesus; and yet it appears from the testimony of Clement, that he esteemed martyrdom an honourable suffering, though it is the punishment of sins committed either in this life, or in a pre-existent state. Basilides taught that the soul only would be saved; but that the body is in its nature corruptible, and incapable of immortality. As for the spirits of the dead, it is said to have been his opinion, or that of his followers, that they would pass successively into other bodies. Basilides has been falsely accused of believing that actions are indifferent in their own nature, and of allowing and encouraging the practice of wickedness. On the contrary he is represented by those whose testimonies are most credible, as strongly recommending the practice of virtue and piety, and condemning not only the actual commission of sin, but even every inward propensity of the mind to a vicious conduct.

However, some of his practical opinions gave offence to the orthodox Christians; for he allowed men to conceal their religion, and even to deny Christ, when their lives were in danger, and to partake of the feasts of the Gentiles that were instituted in consequence of the fastes offered to idols: not to add, that the irregular lives of some of his disciples seemed to justify the unfavourable opinion that was entertained concerning their master. The Basilidians have been also accused of magical practices; but Tertullian says nothing of this kind; and the passages of Irenæus upon which this charge is founded, is supposed to have been corrupted. Besides, the ancient fathers perpetually confound alchemy and astrology with magic; and hence Lardner is induced to be very doubtful about the truth of this acculation. Irenæus says, that the Basilidians called the prince of the heaven Atraxas that name having in it the number 365: and the greeks, or figures, bearing this name, are supposed to have originated from Atraxas. However, many of these Egyptian titles appear to have an earlier date; and the magic of this sort was probably so much more than the practice of certain superstitions, rather of a foolish than of a malignant nature. See ATRAXAS.

BASILIDIANS, the followers of Basilides, of whom an account has been given in the preceding article.

BASILINEA, in Entomology a species of Pulazon, that inhabits Austria. The wings are grayish brown undulated, with a little black line at the base; crest of the thorax bi-colored. Fabricius.

BASILINOPOLIS, or Basildopolis, in Ancient Geography, an episcopal town of Asia Minor, in Bithynia.

BASILIPOTAMO, in Geography, the ancient Euxine, a river of the Morca in European Turkey, which falls into the gulf of Chioschon.

BASILIPPUM, in Ancient Geography, a town of Briton in Spain, about 20 miles from Hispili or Seville; now Can tilia, a cancer of Andalusia, on the Guadalquivir.

BASILIS, a town of Peloponnes, in Arcadia, founded, according to Panionius, by Cypros, and situated near the Alpheus. In his time it was in ruins, among which was a temple of the Eleanian Ceres.

BASILISCUS, in Ornithology, one of the synonymous names of the golden-crowned ken, among old writers. This name is a diminutive of the word basilus, king; and was given it on account of its golden crown.

BASILISCU, in Zoology, a species of Lacerta, which, according to Linnaeus, has the tail long and round; dorsal fin radiated; and back of the head crest. This is the basilisk of modern naturalists, and seems to unite the two genera of Lacerta and Draco. The remarks of Dr. Shaw (in the Gen. Zool.) on this extraordinary creature are highly interesting, and ought not to escape attention. It is, according to this writer, particularly distinguished by a long and broad wing-like process or expansion continued along the whole length of the back, and to a very considerable distance on the upper part of the tail, and furnished at certain distances with internal radii analogous to those in the fins of fishes, and still more so those in the wings of the draco vols, or flying lizard. This process is of different elevation in different parts, so as to appear strongly muscled and indented, and is capable of being either dilated or contracted at the pleasure of the animal. The occiput, or hind part of the head, is elevated into a very conspicuous pointed hood, or hollow crest.

Notwithstanding its formidable appearance, adds this author, the basilisk is a perfectly harmless animal; and like many others of the lizard tribe, refines principally among trees, where it feeds on insects, &c. It has long ago been admirably figured in the work of Seba; and as it is an extremely rare species, has sometimes been considered, from the strangeness of its form, as a fictitious representation. There is, however, in the British Museum, a very fine speci ment, well preserved in spirits, and which fully confirms the excellence of Seba's figure; from which, in all probability, Linnaeus himself (who never saw the animal) took his specific description. The colour of the basilisk is a pale ci-
BASILISK is also mythically used by the alchemists, to denote the lumbarine mercury of the philosophers.

BASILISK, or BASILISK, in Artillery, also denotes a great piece of ordnance; thus denominated from its resemblance to the supposed serpent of that name. The basilisk throws an iron ball of two hundred pounds weight. It was much talked of in the time of Soliman, emperor of the Turks, in the wars in Hungary; but seems now out of use. Modern writers also give the name basilisk to a much smaller and sizeable piece of ordnance, which the Dutch make fifteen feet long, and the French only ten. It carries forty-eight pounds.

BASILISIUM FLUMEN, in Ancient Geography, a river of Asia, which, according to Strabo, flowed between the Euphrates and Tigris; but Ammanus Marcellinus says, that it was a branch of the Euphrates, directed towards Ctesiphon, and designed for conveying water into the interior part of Babylonia. The emperor Trajan and Severus opened this canal after it had been filled up, and formed by it a communication between the Tigris and Euphrates.

BASILIIUS, in Biography, a physician and monk of Bulgaria, in the 12th century, was the founder of the sect called Bogomil. After teaching his doctrine many years in secrecy, he was seduced to Confianinople by the emperor Alexis Comnenus, who, under pretence of learning his doctrines at a private audience, placed a secretary behind a curtain, who penned down what Basilius delivered. The emperor afterwards convoked a council, which, on the refusal of Basilius to retract, committed him to the flames in 1118. See Bогоmил.

BASILUZZO, in Geography, one of the Lipari islands in the Mediterranean, about two miles in circumference, and raised some poles above the surface of the sea. On the south side is a narrow bay; and on the summit is a plain of no great extent, and the only part capable of cultivation, though it produces only a little corn and pulses. This scanty vegetation is nourished by a thin crust of decomposed lava, under which is soon discovered the solid lava, which, in many situations, is granitious, the quartz, felspar, and micas, being very apparent in it. Two little cottages, which belong to the proprietors of this ungrateful soil, are the only buildings, near which are some ancient ruins. Rabbits are the only animals found in this island; and as they were very mischievous to the corn, the inhabitants introduced cats, which followed them into their subterranean holes. This island, as well as those that are in its vicinity, have been produced by volcanic fires. Spallanzani's Travels in the Two Sicilies, vol. ii. p. 142, &c.

BASIN OF MINAS, a body of water of considerable extent and irregular form, situat in Nova Scotia, at the sail end of the bay of Fundy, and connecting with its north-east branch by a short and narrow strait. The country on its banks is generally a rich soil, and is watered by many small rivers. The foraging-tides rise to 40 feet.

BASINET. BACINET, or BASINET, in Ancient Armour. A species of light helmet, much used, both here and abroad in the thirteenth and fourteenth centuries. Its name was undoubtedly taken from its form, and means a little basin. The helmet of Don Quixote gives the reader an exact idea of it. In the manuscript illuminations of the times it frequently occurs; but as it materially differed from the flate helmet, it is rarely, if ever, found upon sepulchral monuments. Fauchet (Œuvres, f. 524. edit. 1610.) cites Froissart (vol. iii. c. cxix.), to prove that it had a visor like the helmet; and observes, that the French warriors of that era thought the bell lances came from Bourdeaux, and the bell helmets and bas nets from Paris, where, in his time, a "Rue de la Haumeière" existed. The basinet is particularly mentioned in the statutes of Robert king of Scotland; and its frequent use in England may be judged of from an inquisition, 22 Edw.
BASINGSTOKE, or Basing, John, in Biography, a man of distinguished learning in the thirteenth century, was born at Basing-floke in Hampshire, and educated partly in the university of Oxford, and partly in that of Paris. From Paris he travelled to Athens; and on his return to England, brought with him a great number of Greek MSS., and introduced the use of the Greeknumerical figures into this kingdom. He was eminentiy instrumental in promoting the study of the Greek language: and with this view he translated from the Greek, into Latin, a grammar, which he intitled "The Donatus of the Greeks." His works were "A Latin translation of the Harmony of the Gospels," a volume of Sermons; and "A Latin Commentary upon Lombard's sentences." He was preferred first to the archdeaconry of London, and afterwards to that of Leicetster; and died in 1272. Gen. Dict.

Basingstoke, in Geography, a large populous town of Hampshire, in England, 16 miles N.E. of Winchester, and 45 W. from London, whence it is a great thoroughfare to the western counties. It appears that this place was of inferior consideration to Basing, in its neighbourhoud, previous to the conquest; the latter place being the head of the barony of Ports. In 1213, Peter de Rupibus, bishop of Winchester, was possessor of the advowson of both the churches, and gave the presentations to the priory of Selborne in Hampshire. These afterwards were given, among other clareses, by bishop Wainfleet to Magdalen college, Oxford, in which the patronage is now vested. In the church lies buried the mother of Walter de Merton, bishop of Rochester, founder of Merton college. Basing-floke gave birth to John de Basing-floke, a learned Greek scholar, in 1252, and the intimate friend of Matthew Paris, and bishop Grosboul. Henry III., at the desire of bishop Merton, founded an hospital at this place for aged priests from his college at Oxford: of this collegiate church, which was endowed in 1261, there are now no remains. A beautiful ruin overlooks the town on the north side, called Holy Ghost chapel. This was founded by sir William, afterwards lord, Sandes, who, with bishop Fox, obtained a licence from Henry VIII. to found a brotherhood, to continue in perpetual secession, for the maintenance of a priest to perform divine service, and for the instruction of youth in literature. The town is a corporation, governed by a mayor, high-steward, recorder, &c. Its trade consists in the manufacture of druggists and shalloons; and the market, held on Wednesday, is very considerable for corn; the trade of the town is much benefited by a navigable canal. Basing house, in this neighbourhoud, is rendered famous by the bold stand its possessor, Powlet marquis of Winchester, made against the parliament forces, during the civil wars in the reign of Charles I. Population; houses 512, inhabited by 2589 persons.

Basingstoke Canal. This was the first channel of communications with the Thames, by means of canal navigation: and in 1777, an act was obtained for uniting the waters of the river Loddon at a place called Newman springs, near the village of Basing, to the river Wey, near Weybridge in Surrey, where it falls into the Thames. One important object of this canal is the carriage of ship-flimber from the woods in Hampshire, to the public and private docks on the Thames. The length of the course of Basing-floke canal is nearly 44 miles. Warner's History of Hampshire, 4to. See Canal.

BASIOGLOSSUS MUSCLE, in Anatomy, the front part of the Hyoglossus; which see.

BASJOURA, in Geography. See Baghura.

BASIRE, or Basier, Isaac, in Biography, a learned and active divine in the fourteenth century, was born in 1607, according to Wood (Athen. Oxon.), in the Isle of Jersey, but according to others in France, and after an education in some school or university, not ascertained, he became master of the free-school at Guernsey. At length he obtained some preferments in England, the last of which was the archdeaconry of Northumberland, with the annexed rectory of Howick; and in 1640, he received the degree of doctor in divinity at Cambridge by mandate. In the beginning of the civil war, he was plundered and compelled to fly; upon which he repaired to King Charles at Oxford, and in 1641, a licence was granted to him, under the public seal of the university, to preach the word of God throughout England. Upon the surrender of Oxford to the British parliament, he determined to leave the kingdom, and to propagate the doctrine of the English church among the Greeks, Arabsians, &c. Accordingly, he first went to Zante, an island near the Morea, and thence imparted to the Greek inhabitants the doctrine of the established church, in a vulgar Greek translation of our church catechism. From hence he was compelled by the Latins to retreat to the Morea, where, at the desire of the metropolitn of Achaia, he preached twice in Greek, at a meeting of some of the bishops and clergy. He afterwards embarked for Syria, and during his abode at Aleppo, furnished the patriarch of Antioch with an Arabic translation of our church catechism. From Aleppo he travelled, in 1652, to Jerusalem, and through the whole of Palestine. At Jerusalem he was honoured by the Greek patriarch with his bull, or patriarchal seal, and he received many tokens of respect from the Latins. At this departure from Jerusalem, the pope's vicar gave him his diploma in parchment, under his own hand and seal, in which he was styled "a priest of the church of England, and doctor of divinity." On his return to Aleppo, he passed over the Euphrates into Mesoopotamia, intending to convey the church catechism in Turkish to some of their bishops, who were mostly Armenians. In 1653, after wintering at Aleppo, he travelled by land to Constantiopole, where the Greek Prototypes desired him to be their minister, promising to secure to him a competent stipend. Before he quitted the Eastern parts, it was his intention to have passed into Egypt, to visit the Coptic churches, to confer with the patriarch of Alexandria, and to impart to them a competent knowledge of the doctrines and forms of the church of England. But it is not known whether he accomplished this design. In Transylvania, whither he next removed, he was honoured by Ragotski, prince of that country, with the divinity-chair in his new-founded university of Alba Julia or Weissenburg, and endowed with a very ample salary. During his travels, he collated the several confessions of faith of the different sects of Christians, Greeks, Armenians, Jacobites, Maronites, &c. which he kept by him in their own languages; and it was his constant endeavour, as long as he remained in the East, to persuade the several sects of Christians to introduce a canonical reformation of some errors, and to unite with the church of England. But it is said, that his good intentions for this purpose were defeated by the artifices of the court of France. Upon the restoration of king Charles II., Dr. Bafire was recalled by his majesty to England, and restored to his preferments and dignities. Having quietly enjoyed his ample revenues for several years after the restoration,
he died in 1676, in the 6th year of his age, and was buried in the yard belonging to the cathedral of Durham. He appears to have been learned, active, and industrious, zealously attached to the church of England, and eminently distinguished by his loyalty. His publications were not very numerous: the principal of them were his "Deo et Ecclesiae Sacrum," or sermons arranged and condemned by St. Paul, Oxford, 1664, 4to, and London, 1663, 8vo; "The History of the English and Scotch Presbyteries," 1 Lord, 1630, 1631, 1652, 8vo; "The Deed man's real speech," a funeral sermon for Dr. Cullen, bishop of Durham, to which is annexed his life; Lond. 1673, 8vo; and his "Deo et Ecclesiae Sacrum, Ecclesiae Britanniae Libertas," printed at Bregus by a royal licence in 1676, 8vo, and translated into English under the title of "The ancient Liberty of the British Church, &c." Annexed to it is "A Letter, written by Dr. Bafei the Hon. Sir Brown, resident at Paris for his majesty of Great Britain; relating his travels and endeavours to propagate the knowledge of the divine and disciplinary established in the British church, among the Greeks, Arabsians, &c. dated from Paris near Constantinople, 20th July 1653." Of this letter R. Brown oberves, that he could never read it but as a kind of nine-and twentieth of the Acts." This book was printed at London in 1661, small 8vo. Biog. Brit.

BASIS, in the Ancient Mefie and Poetry, denotes the equality of sounds preceding in the same tenor. In which sense, baifs stands contradistinguished from aules, or elevation, as well as from the, or depression. Basis, in Architecture and Chemistry, see BASE.

Basis, in Oratory, denotes the fourth member of a complete exordium, being that which succeeds the apodosis, and prepares the way for the proposition.

BASKERVILLE, Sir Simon, in Biography, son of Thomas Baskerville, an apothecary at Exeter, was, at the age of eighteen years, sent to Exeter college, Oxford, where he soon distinguished himself by his superior ability and industry, which procured him a fellowship in the college before he had taken his degree of bachelor in arts. In 1690, he was chosen senior prebend in the university. He now applied himself solely to the study of anatomy and physiology; and in 1691, was admitted to the degree of bachelor, and doctor in medicine, at the same time. Having acquired considerable reputation for his skill in his profession, he removed to London, and was chosen fellow, and some years after president of the college of physicians there. He had also the honour of being appointed physician to King James, and afterwards to King Charles the first, by whom he was knighted. As his practice extended with his fame, he acquired so much wealth as to be called the rich Sir Simon; which will not be wondered at, if it be true, as was reported of him, that he had 100 patients on his list at a time. He died July 5th 1641, aged sixty-eight years, and was buried in the cathedral of St. Paul's. It does not appear that he left any manuscripts for publication, or any offering to inherit the wealth he had accumulated. Wood's Athenae Oxon. Biog. Dect.

BASKERVILLE, John, an ingenious artist, entitled to commemoration on account of his improvements in printing and type-founding, was born at Woveley, in Worcestershire, in the year 1700, and inherited a small estate. Having acquired in early life a skill and taste for fine writing and cutting in stone, he removed to Birmingham at the age of twenty, where he settled as a writing-makir; but he soon directed his attention to the art of japanning, which he followed with singular ingenuity and success as long as he lived. In 1750 he turned his thoughts to letter-founding, which he pursued with great labour and expense. An edition of Virgil in royal 4to., in 1756, was his first great performance; which has since fetched three times its original price. He afterwards printed many of the Latin classics, and several English ones, in 4to. and smaller sizes. The paper and ink, as well as the type, were prepared by himself; and the beauty of his workmanship was unrivalled. The type was distinguished by a peculiar fineness and sharpness, which gave the printing a strong resemblance to fine pen and handwriting; and the paper had a remarkable gloss, which set off the type, but not without offending the eye. It is observed, however, that Baskerville's editions are not remarkable for their correctness. Driving little encouragement from book-sellers, he set up a type-foundery for fine, which business was for some time carried on by his widow, after his death in 1757. After many ineffectual attempts for the disposal of his types and matrices, they were suffered, not much to the credit of this country, to be removed to Paris, where they were purchased by a literary society for 5700l., and employed in a splendid edition of Voltaire's works. Mr. Baskerville was distinguished by the elegance of his taste in his house, and every thing that belonged to him. The panells of his carriage were elegant pictures, and he was drawn by a beautiful pair of cream-coloured horses. He seems to have been inclined to ostentation and singularity: however, he was polite and hospitable to strangers, and ambitious of cultivating acquaintance with ingenious men. He was not connected with any religious fact, and was buried under a mausoleum in his own grounds. Biog. Brit. Gen. Biog.

BASKET, a kind of vessel made of oiler, wicker, rushes, or the like, of different figures and sizes, according to the purpose which it is intended to serve. Basket have their use not only in the economical, but military affairs; at sieges, they make use of a small basket filled with earth and ranged on the top of the parapet. They are about a foot and half high, as much in diameter at top, and eight or ten inches at bottom; so that being set together, they leave a sort of embrasures at the bottom, through which the soldiers fire, without exposing themselves.

BASKET also imports a kind of measure or quantity of certain commodities.

BASKET, corbel, in Architecture, a kind of vaise, or figured piece of sculpture, in form of a basket, filled with flowers or fruits, serving to terminate some decoration.

BASKET, a kind of vessel, in Natural History, a name given by the English in North America, to a very remarkable fish, sometimes caught in the Fass river near, though not frequently any where.

Mr. Hooke, to whom it was referred by the Royal Society to name it, has called it Ficis celossephallus xaliformis, the body of it refumbling an egg-fish, or ebonius marinus, and the arms a flat fish, and finally, the dividing of the branches being more like that of the branches of a tassel than any other natural production we are acquainted with.

This fish spreads itself from a pentagonal mouth-piece, or root, in the centre of which the mouth is placed, into five main limbs or branches, each of which, at its first issuing out of the body, is divided into two; this makes ten. Each of these ten again divides into two, which makes twenty, and so on, each dividing to the fourteenth time; at which place they make more than four thousand limbs. These are too small to be traced farther by the eye, or preferred to the grass, but it is very probable that even these were again divided, perhaps several times.

The branches between the joints are not all equally of a length, though, for the most part, they are pretty nearly so. The arms or branches are never very strong; but when they are
are dry, they are much more brittle than before; the lead force imaginable destroying them.

The floods of Nantucket, an island on the coast of New England, at times furnish the fishermen with this creature; but it is remarkable, that they are never seen there unless when taken by hooks in fishing for other fish. They clap the back-bait fall, and encircle it with all their arms, coming up, when drawn by it, in form of a wicker basket, whence the name: but when they have been some time out of the water, they become flat.

The use of the numerous arms of this fish is plainly to catch its prey. It probably extends them to their full length while under the water, and then claps hold of any thing fit for food that chances to pass over them. The fishermen have sometimes found the arms containing small encased, or pieces of large r. Phil. Trans., No. 57 and 74. It is evident from the description, that this fish is of the stella arboriformis, or branched-fish-kind; but whether the name with the commonly known kind, called the capitale medusa, is not evident from this description. The body of this fish, by what is reined of its preteronomy, and resemblance to the echinodermata, may probably be the afterpallium in its full state.

See Asterias, and Asteropodium.

Basket fish. This is a brittle fish, made from the water of our salt springs in Cheshire, and elsewhere, differing from the common brine-fish in the finness of the grain, and in its whitish and purity.

In the preparing of this kind of fish, some use thin, and other additions, to break the grain and make it small; other effect this by keeping up a very brisk fire under it, and stirring it all the while: but the most approved method is only to take out of this kind the third draught of every pan that is working for the common brine-fish, and to do this before the granules are yells are perfectly formed. By this means the flake is very fine: and when it has been hard pressed down into small wicker baskets, it is dried at the close in them, and so kept for sale.

Basking Shark, in Ichthyology, the English name of Squallus Maximus.

Baskindridge, in Geography, a town of America, in Somerset county, New Jersey, on the W. side of a N.W. branch of Patassic river, nearly 6 miles N. E. from Pluckemin, and 7. 8. W. from Morristown.

Basnage, Benjamin, in Biography, son of a French minister, was fattened at Norwich, in England, and afterwards at Charenton, in Normandy, was born in 1701, and devoting himself to his father's profession, succeeded him at Charenton, where he spent the remainder of his life. In 1743 he assisted at the synod of Charenton, as deputy from the province of Normandy, and he was chosen, on account of his distinguished talents and prudence, moderator of the national synod of Alcoron, in 1737. He was afterwards associated to the moderator of the synod of Charenton in 1744, and being deputed by this synod to the queen-mother, received from her tokens of esteem. He was also deputed by the Protestant churches in France, to king James VI. of Scotland: and being allowed to visit that country, he was eminently useful in serving the interests of his co-religionists. Bafrage had several disputes with the Catholics, and wrote "A Treatise on the Church," which was much esteemed. He also left an imperfect "Work against the indirect worshippers of the blessed Virgin." He died in 1748, in the fifty-fourth year of his ministry, and left two sons of distinguished merit, Gen. Dict.

Basse, Antony, eldest son of the former, was born in 1702, and became minister of Bayeux. He distinguished himself by his sermons and resolution during the persecution of the protestants; and after having been imprisoned at Havre-de-Grace, at the age of 25 years, he was released by the revocation of the edict of Nantes, and fled to Holland. He died at Zutphen in 1761, Gen. Dict.

Basnage, Henry, younger son of Benjamin, was born at Sainte Mere Elice, in Lower Normandy, in 1675. Educated to the profession of the law, he became one of the most learned and eloquent advocates of the parliament of Normandy, into which he was admitted in 1693; so that he was employed in every cause of importance. In 1727 he was appointed commissioner for the affairs of religion, and discharged the office with great honour. He was highly esteemed as an author, as well as an advocate: and in 1703 he published the "Histoire de Nantes," with ample commentaries, of which a second edition, in 2 vols. 8vo, was published in 1704. At the same time was published a third edition of his "Traicts des Hypothoques," a Treatise on Mortgages. He died at Rouen in 1705, Gen. Dict.

Basnage, Samuel, de Flottemansville, son of Anthony, was first co-pastor with his father at Bayeux, and afterwards at Zutphen. He was eminent for his learning; and published in Latin a continuation of Cafaarau's Critical Examination of Baronius's Annals, entitled "De Rebus Sacris et Ecclesiasticis Exercitationes Historico-criticae." Ultragot. 4to. 1622; and also "Annales Politici Ecclesiasticâ," 3 vols. folio, 1706. He died in 1721, Gen. Dict. Nov. Dict. Hill.

Basnage de Beauval, James, eldest son of Henry, the most illustrious of the name, andifter, says Voltaire, for being minister of state than of a pariah, was born at Rouen in 1673. Having acquired a competent knowledge of Greek and Latin, and several modern languages, he went, at the age of fourteen, to Geneva, where he studied philosophy and divinity. Upon his return to Rouen, he commenced the exercise of his profession as pastor of the church in 1716, and in consequence of the revocation of the edict of Nantes, retired to Holland, and settled as minister at Rotterdam. Such was the reputation he acquired for political sagacity, that when the Abbe de Bevis came to the Hague, in 1706, under the character of ambassador penipotentiaire, to negotiate a defensive alliance between France, England, and the States-General, he was ordered by the duke of Orleans, regent of France, to consult Mr. Baunae, and to be directed by his advice: and as a reward for his assistance on this occasion, he obtained a restitution of his estate in France. His works are very numerous and valuable: the principal are as fall, v. "A History of the Church," in French, 2 vols. Rotterdam, 1699; "The History of the Reformed Churches," part of the above work, printed separately in 2 vols. 1721, "The History of the 4. from Jesus Christ to the present time, being a continuation of the history of Jesus," written in French; of this work, distinguished by erudition and critical skill, the best edition is the second of the Hague, in 15 vols. 12mo. 1716; "The Republic of the Hebrews," 3 vols. 8vo. Amst. 1705; "Jewish Antiquities," 2 vols. 8vo. 1713; "Disputation on Duels and Chivalry," 1720; "Annotations of the United Provinces, since the Peace of Nimy," 2 vols. fol. Hagen, 1719 and 1720; "A Treatise on Confession," 2 vols. 8vo.; "Sermons." "On the Holy Communion," "The Farmer in Anniversary, Ecclesiasticorum et Historiorum, 8e," fol. 4 vols. Amst. 1735. Being a new edition of "The Letters of Antiques" of Henry Castruis, enriched with learned prefaces and remarks. The matter of Basnage is good, but his style, though sufficiently perspicuous, is stiff and inelegant. In the latter part of his life he removed to the Hague, and died there in 1723. He was polite and affable, benevolent and friendly, and more mild in his disposition than most cont.

Bassage de Beaulay, Henry, younger brother of the preceding, was born at Rosay in 1653, and became a counsellor in the parliament of Normandy. Attached to his religious profession, he quitted his prof-ets at the bar, and took refuge in Holland, where he published, in 1684, a small but valuable treatise "On Religious Toleration." He also wrote a sequel to the " Nouvelles de la Republique des Lettres" of Bayle, under the title of "L'Histoire des Ouvrages des Savants," commencing in 1657, and concluding in 1709, and comprising 23 vols. 12mo. This work is reckoned judicious and impartial, but the writer's observations are sometimes so intermixed with those of the authors whose works he reviews, that they cannot be easily distinguished. His new edition of "Fourier's Dictionary," 3 vols. 4to, was printed in 1701.

Bason, Pelvis. See Pelvis.

Bason, or dish, among Glass Grinders. These artificers use various kinds of basons, ofopper, iron, &c. and of various forms, some deeper, others shallower, according to the foot of the glafls that are to be ground. In these basons convex glafls are formed, as concave ones are formed on spheres or bowls.

Glafls are worked in basons two ways. In the first, the basin is fitted to the arbor, or tree of a lathe, and the glafls (fixed with cement to a handle of wood) are fitted and held in the right hand within the basin, while the proper motion is given by the foot of the basin. In the other the basin is fixed to a fland or block, and the glafls with its wooden handle moved. The moveable basons are very small, seldom exceeding five or fix inches in diameter; the others are larger, sometimes above ten feet in diameter. After the glafls have been ground in the basin, it is brought smoother with grease and emery; and polished first with tripoly, and finished with paper cemented to the bottom of the basin. See Grinding.

Bason, among Hatters, is a large round shell, or cafl, ordinarily of iron, placed over a furnace; wherein the matter of the hat is moulded into form. The hatters have also basons for the brims of hats, usually of lead, having an aperture in the middle, of a diameter sufficient for the largest block to go through.

Bason, in Hydraulics, is also used on various occasions for a small receptacle of water: as the basin of a jet-d'eau, or fountain: the basin of a port, of a bath, &c. which lift Vitruvius calls labrum. Basons are made either with clay, cement, or lead; but they are most usually made with clay. In the making of them this way, the diameter must be made four feet longer on each side than the basin is to be. This will be taken up by the walls of cly. For the same reason, it must be dug two feet deeper than the intended depth of the water; because it is to be laid over eighteen inches thick with clay, and fix inches with gravel and paving. The wall is to be made with shards, rubbiff, or flints, with the natural care for mortar; and the clay must be well worked, and tied firmly down with the naked feet.

The way of making them with cement, is, to allow one foot nine inches every way for the work; then cut the banks perpendicularly, and raise a wall of masonry a foot thick, made of pebble dous, or the like, laid in mortar of lime and sand: the bottom is then to be covered to the fame thickness; and then the solid lining of the cement is to be backed up against the walls, and over the bottom. This is to be made of small flints in beds of mortar made of lime and cement. When this is fixed eight inches thick, it must be plastered over the whole surface with cement well fitted, before it be mixed with the lime; and with this it is to be wrought over smooth with a trowel. The proportion of this cement should be two-thirds of the cement, or powdered tile, to one-third of lime; and this cement has the property of hardening under water, that it will become like stone or marble, and it will not be subject to decay for a long time.

After the finishing, the basin should, for four or five days, be annealed over very often with oil, or barrack's blood, to keep it from flawing or cracking in the drying; and after this, the water should be let in as soon as may be.

The leaded basons are made with walls two feet thick, and a bottom of half a foot. These must be of rubble stones, cemented with plaster; for the lime will injure and eat the lead. The sheets of lead are to be spread over these walls and bottom, and strained with folder. These basons, however, are but little in use now, from the expense of making them, and the danger of the lead being stolen.

The wafer pipes of fountains ought always to be made large enough for fear of choking. When the wafer water is to be carried off into common fowers, it may be carried away by drains, or earthen pipes; but when it is to serve for basons that he below it, it is to be conveyed in leaded ones.

Miller.

There are divers sorts of basons; as

Bason figured. that whole plan or circumference makes several turns and returns, either straight, circular, or the like. Such are most of the basons of fountains at Rome.

Bason with a balustrade, that whose cavity is surrounded with a balustrade of stone, marble, brass, or the like. Such is the fountain of the rock of the Belvidere at Rome.

Bason en eysthile, that shaped like a shell.

Bason is likewise used for a Dock.

Bason of the sea. See Sea.

Bason, fall by this, in Commercet, at Amsterdam, is used for the public fakes made under the direction of the van den meffer; thus called, by reason that, before adjusting the irons to commodity of the last bidder, they usually flake a brass basin to give notice of it.

Bason harbour, in Geography, lies on the east side of Lake Champlain, in the township of Ferrisburg, and state of Vermont, 4 ½ miles south-west from the mouth of Otter creek.

Basons of a balance, in Mechanics, two pieces of brass, or other matter, fastened to the extremities of the springs; the one to hold the weight, the other the thing to be weighed.

Basova, in Geography, a town of Siberia, on the river Lena, 20 miles south of Orients.

Basouda, a large town of Hindostan, belonging to the district of Bhilah, in the route from Agra to Oujen.

Basques, Liis, a country of France, before the revolution, situate between the sea, Spain, the river Adour, and Bear towards the Pyrenean mountains, and comprehending Labour, Lower Navarre, and the district of Soule.

BASQUE ROAD lies on the coast of France, south-east from the island of Rhé, north-east from the island of Oleron, north from the island d'Aix, and south from the west point of the entrance into Rochelle, and directly west without the bay of Chateauxillou.

BASKEVILLE, a town of France, in the department of the Lower Seine, and chief place of a canton in the district of Dieppe, 3 leagues S.S.W. of Dieppe, and 73 N.N.W. of Rouen.
BASRAH. See BASSORA.

BASROUCHE, a town of Persia, in the province of Taberlitian, 27 miles west of Farabat.

BASS, among Gardner's, a soft kind of fledge or ruff, used in binding plants, &c.

Bass, in Geography, an island, or infalutated rock, on the coast of Scotland, near the mouth of the Firth of Forth, at a small distance from the town of North Berwick in East Lothian. On the south side it has a conical form, and towards the north it is scarcely overtopped by the sea. The castle, or ancient flat prison, is on the edge of the precipice. It is accessible only on the south-west side, and here only by one person at a time, with the assistance of a rope or ladder. On the top of it is a spring, and a cavern passes through the rock from south-west to north-east. This island is about a mile in circuit, and in summer abounds with birds and their eggs, &c. The island garrison arrived here in March, and retired in October or November. It contains a small warren for rabbits, and affords pasture for a few sheep. At the revolution it was supported by a party of the adherents of King James, and it was the last place in the three kingdoms that submitted to the new government; upon which its fortifications were neglected. This island is the first entrance into the Firth of Forth; and the island of May, seven miles from it, at N. E. callder is the north entrance. N. lat. 56° 3/°, W. long. 2° 33'.

Bass Harbour, a harbour of Mount Desert island, in the district of Maine, North America, seven miles from Seal Cove.

Bass Strait, so called from its discoverer Mr. Baf, a surgeon, is more than 50 leagues wide, containing a chain of small islands that run north and south, and separates Van Diemen's land, hitherto considered as its southern extremity, from New Holland. Mr. Baf, accompanied by Mr. Flinders, a naval gentleman, entered this strait between the latitudes of 39° and 40° south, and actually circumnavigated Van Diemen's land. This discovery serves to expedit the passage from the cape of Good Hope to port Jackson; for although a line drawn from the cape to 44° of south latitude, and to the longitude of the south cape of Van Diemen's land, would not feasibly differ from one drawn to the latitude of 40°, to the same longitude; yet a ship will be four degrees nearer to port Jackson in the latter situation, than in the former. But besides a saving of four degrees of latitude along the coast, the passage through this strait would avoid the north-eaft winds, which have retarded and endangered ships on opening the sea round the south cape and cape Pillar. This strait likewise presents another advantage. From the prevalence of the north-eaft and easterly winds off the south cape, many suppose that a passage may be made thence to the westward, either to the cape of Good Hope or to India; but the fear of the great unknown height between the south cape and the south-west cape of Lewen's land, lying in about 35° south and 130° east, has hitherto prevented the trial from being made. The strait evades a part of this danger, by presenting a certain place of retreat, should the ship be opposed by a gale at the first entrance; and should the wind come at south-east, the need not fear making a good stretch to the W. N. W., which course, if made good, is within a few leagues of going clear of all. There is besides King George the Third's found, discovered by Capt. Vancouver, lat. 35° 3', and E. long. 118° 14'; and it is hoped, that a few years will diffuse many others upon the coast, as well as confirm or otherwise that a strait larger than Baf's strait dismembers New Holland. Collinson's account of New South Wales, p. 197, 198.

BASS, in Music. See BASS.

BASAD, or BASS, an Arabian name for the purple fucus of the Greeks, used by the women to paint their cheeks, and by the dyers of clothes. It has been so far confidered by late authors as to be interpreted by the word coral, but the error of this is evident, since coral has none of these properties. See MARGIAN.

BASSAIL, in Geography. See BASSENE.

BASAMUER Rock lies on the coast of France, in the English channel, and is a head that bears about a league N. by W. from La Carte church, near the point so called, to the south from the seven islands.

BASSAN, Giacomo, in Biography, a celebrated painter, whose real name was Giacomo de' Ponte, was called Bassan from the town of Bassano on the river Brenta, where his father lived and followed the same profession. He was born in 1516, and became a disciple of Bonfiglio; and after having improved himself in his art by studying and copying the works of Titian and Parmigianino at Venice, he returned to his native town. Here he formed a style different from that of his masters, and guided by his own genius, he assumed a manner of colouring and designing peculiar to himself, and copied all his objects from nature. His subjects were generally taken from such parts of Scripture as afforded the rural scenery of animals and landscape connected with some story; such as the jouneyings of the patriarchs, the Israelites in the desert, the flight of Joseph and Mary into Egypt, &c. In all these subjects his figures were well designed; most of them were formed from his wife, children, and servants, and the animals in his court-yard; and they had of course a picturing resemblance of nature. Although his compositions cannot boast of any great degree of elegance or dignity, they are distinguished by force and truth; his colouring was admirably lively and natural; and his chiaro- and carce were correctly displayed. His touch was free and spirited; and in his landscapes his distances were always true. Although he had many excellencies, his drawing was incorrect, and his draperies were delineated of variety. His works are easily distinguished from those of other painters, by the similarity of characters and countenances in the figures and aimals; by his talent in the buildings, utensils, and draperies; and by a violet or purple tint that predominates in every one of his pictures. Bassan painted much, and with ease; so that his pictures were not only produced, but also engraven on copper, and advertised to merchants, who dispersed them over Europe. His real pictures, however, are not common; as many of those that are called originals are copies by his sons, who were inferior to himself, or by some painter of meaner abilities. Bassano practised also in portrait, and painted several excellent likenesses of the doges of Venice, of Ariolito, Taffo, and other persons of eminence. His house at Bassano, to which he was attached, and which the embellishments of the emperor Randolph could not induce him to leave, was the place of resort to many persons of distinction, and the recipient of the arts, particularly of music, of which he was a master. In his private conduct Bassan was regular; and his charity was so profuse, that his wife was under a necessity of restraining his liberality. He lived to the age of 82, and died in 1592. Several of his capital pieces are in the churches of Bassano, Venice, Vicenza, and other towns of Italy. Some of his smaller works may be found in most of the principal collections of Europe; but those that are really originals fetch a high price. Many of them have been engraven.

Giacomo Bassan had four sons, who were painters. Francesco, the eldest, was the most eminent. He was born in 1550. He painted in the style and manner of his father.
and greatly excelled his brothers in designing, drawing, and colouring. He was employed in the church of St. Mark at Venice, in conjunction with Tintoretto and Paolo Veronese. By incessant application he increased the natural melancholy of his disposition, and put an end to his life in 1554, by throwing himself out of a window. *Lambro was born in 1528, fled from Venice, painted in the style of his father and brother, but with inferior mark, and particularly excelled in portraits. The portrait of the dog, Germani procured for him the honour of k. lighthood. His life was irregular, and he delighted himself by a constant suspicion of the intention of his companions to poison him. He died in 1623. The other two brothers, viz. Giovanni Battista and Giovanni, the former born in 1553 and dying in 1611, and the latter born in 1562, and living in 1622, chiefly employed themselves in copying the works of their father and eldest brother. *Pukkonen.

BASSANI, Giammatita, in Musical Biography, was chiefly known in England, at the beginning of the 17th century by his Melos, which were more graceful and pleasing than those of any of his countrymen, except Corelli and Stradella. But he has many titles to honourable place in musical history. He was not only author of thirty—seven different works in favour all over Europe during the limited longevity of musical productions, but the chief composer for the violin in Italy, who seems to have written for it with the spirit and intelligence of a real master of the instrument. He was a native of Bolognae, maestro di capella of the cathedral, Academico Filarmonomico of that city, and violin-maister to Corelli. Baffani, who flourished from about the year 1675 to 1703 (the date of his last work), was a man of extensive knowledge and abilities in his art; having been not only a successful composer for the church, the theatre, and the chamber, but an excellent performer on the violin, as we are assured by Padre Marinii his townsmen, who was old enough to have formed his opinion from those who had often heard him perform. And indeed, his fantasias for the violin, and accompaniments for that instrument to his madrigals, motetas, psalms, and cantatas, manifest a knowledge of the finger-board and bow, which appears in the works of no other composer, anterior to Corelli, which we have been able to find, and the lovers of the pure harmony and simple melody of that admirable master would still receive great pleasure from the performance of Baffani's fantasias for two violins and a bass: in which they would hear, not only the general musical language of the time, but the mild accents and grateful tones of Corelli's own mellifluous voice. *Bassania, in Ancient Geography, a town of Macedonia, on the frontier of Illyria, situate, according to Livy, about 5 miles from Litus, and belonging to the Cevans. *Bassano, in Geography, a town of Italy, belonging to the state of Venice, in the Trevisano, on the Brenta, 12 miles north of Vicenza. *Bassano, a town of Italy, in the state of the church, near which Dolabella defeated the Etrurians and Boils, 3 miles west of Orta. *Bassantin, James, in Biography, a Scots astronomer, in the sixteenth century, was the son of the lord of Bassantin, in the Mers, and born in the reign of King James IV. The rudiments of knowledge, and particularly of that skill in various branches of the mathematics for which he was afterwards so distinguished, he acquired in the university of Glasgow. *For further improvement he travelled through various parts of the continent, and at length settled at Paris, where he taught the mathematics with applause in the university of that city. During his abode in this city, he imbibed that zeal for the delusions of judicial astrology, which was then so prevalent, and which few astronomers had judgment or resolution sufficient to discountenance. *After having acquired great reputation and some fortune in France, he returned to his own country in 1562. At York, in his journey through England, he had an interview with Sir Robert Melvill, brother of Sir James Melvill, who, in his *Memoirs,* relates the conversation that passed between them. *It appears, that Bassantin, after certain predictions relating to his mistress, Mary queen of Scots, who was then treating with Elizabeth after having taken refuge in her dominions. Of these predictions some were true, and others were false; but such was the political sagacity of Bassantin, that we may attribute them to his skill in the occult sciences, from which however he seems to have been ambitious of being thought distinguished. Of his mode of life during the remaining period of it, we have no account; but he appears to have been a zealous protestant, and partisan of the earl of Murray. He died in 1585. To a flight acquaintance with polite literature, Bassantin added a considerable degree of mathematical and astronomical knowledge, conferring the dark period in which he lived. His principal work in astronomy was written in French, and translated into Latin by Turnerius, and published at Genoa in 1599, folio, under the title of *Astronomy.* Jacobii Bassantii Scoti opus absolutissimum, &c. &c. He also published *Paraphrase de l'Afferolab, with an amputation of the ufe of the Afferolab,* or an ample explanation of the afferolab, printed at Lyons in 1553, and at Paris in 1617, 4to; *Super Mathematica Geometrida,* or of the calculation of nativities; *Arithmetica,* *Muficae secundum Platonii,* and *De Mathefi in generere.* *Bog. Brit.*

BASSANUS, in Ornithology, a species of Pelecanus, as large as a common goose, with a wedge-shaped tail; body white; bill and primary quill-feathers black; and face black. *Gmelin. Latham, &c.*

This is the common gannet, or folder gower; a bird found in great plenty along the northern coasts of Brit ain, but rather less common to the southward. The adult birds have the plumage nearly all white; but during the first years it is of a dusky colour, and only speckled with white. The bill is blue-buff colour, about six inches in length, and has the nostrils placed in a row; the mouth is black; the throat is bare; and the skin very dilatable, forming a pouch of suffet at size to contain five or six herrings; the legs are black, marked with a stripe of pea-green before; and the claw of the middle toe is pronounced. The males and female are very much alike in plumage. The gannet is particularly abundant in the isle of Ailsa in the firth of Clyde; the rocks adjacent to St. Kild; the bays of Soundberry, near the Orkneys; the Sk of the coasts of Kerry, Ireland; and the Bass island in the firth of Edinburg. Dr. Harvey gives some account of the latter in these words, *There is a small island, called by the Scotch Boys island, not more than a mile in circumference, the surface is almost wholly covered during the months of May and June with nets, eggs, and young birds; so that it is scarcely possible to walk without treading on them; and the flocks of birds in flight are so prodigious as to darken the air like clouds; and their noise is such that you cannot without difficulty hear your next neighbour's voice. If you look down upon the sea from the top of the precipice, you will see it on every side covered with infinite numbers of birds of different kinds, swimming and hunting for their prey; if in sailing round the island you survey the hanging cliffs, you see in every crag or fissure of the broken rocks innumerable birds of various forts and sizes, more than the

BAS
flars of heaven when viewed in a serene night; if from afar you see the distant flocks either flying to or from the island, you would imagine them to be a vast swarm of bees.

"The gannets," observes Dr. Latham, "inhabit the colder parts of this kingdom, and more especially several of the northern islands, and in particular that of Baffin in Scotland, whence the name. It generally first makes its appearance in March; and after making a circuit of the island, departs in October or November. This race seems to be in pursuit of the herrings and pitchards, whose motions it watches; and the herrings know the coming of these fish by the appearance of the birds. That this is the inducement seems probable, as they are liker fish, in the month of December, as far forth as the coast of Labrador and Gibraltar, plunge for it.

The gannet is also common on the coasts of Norway and those of Iceland, and now and then met with on the southern coast of Greenland. In America, it is found on the coasts of Newfoundland where it breeds, migrating in winter as far as Carolina: said also to have been met with frequently in the southern ocean; but we are not clear whether the fort meant by them is the common gannet, or the lesser one.

"The gannets," Mr. Pennant remarks, "are birds of passage. The first appearance in those islands being in March, and their continuance till August or September, according as the inhabitants take or leave their birds; but in general the time of breeding and that of their departure seems to coincide with the arrival of the herring, and the migration of that fish, which is their principal food, out of those seas."—I have in the month of August," he adds in another place, "observed in Caithness their northern migrations. I have seen them palling the whole day in flocks, from five to fifteen in each. In calm weather they fly high, in forms they fly lowest and near the shore; but never cross over land, even when a bay with promontories intervenes, but follow at an equal distance the course of the bay, and regularly double every cape. I have seen many of the parties make a fort of hails for the sake of fishing; then darting headlong into the sea, make the water fur and spring up with the violence of their descent: after which they pursue their route. I enquired whether they ever observed to return southward in the spring, but was answered in the negative; so that it appears, they annually encircle the whole globe.

They are well known on most of our coasts by different names. In Cornwall and in Ireland they are called gannets, and by the Welsh gen. It comes on the coasts of Cornwall in the latter end of the summer or beginning of autumn, hovering over the heads of pitchards that come up through the St. George's channel from the north sea. The gannet seldom comes near land, but is constant to its prey; and when the pitchards retire, which happens about the end of November, they are seen no more.

The nest of the gannet is composed of various materials, such as grass, and water plants intermixed with anything the bird finds floating on the water. Each bird, if undisturbed, would lay only one egg in the year; but if that be taken away, they will lay another; and if that be taken away also, they will lay a third, but no more. The young gannets, as well as the eggs, are eaten. Martin affirms us, that the inhabitants of St. Kilda confine annually no less than 22,000 young birds of this species, besides an amazing quantity of their eggs; these being their principal support throughout the year; they prefer both eggs and fowls in pyramidal stone-buildings, covering them with turf and ashes to prevent them from moisture. This is a dear-bought food, and eaten at the hazard of their lives, either by climbing the most difficult and narrow paths, where to appearance they barely cling, and that too at an amazing height above the raging sea; or else, being lowered down from above, they collect their annual provision, thus hanging midway in the air, and placing their whole dependence on the uncertain footing of one person who holds the rope by which they are suspended at the top of the precipice. The young birds are a favourite dish with the north Britons in general, during the season they are constantly brought from the Baffin land to Edinburgh, and are roasted and fed up a little before dinner as a whet: the price they are sold for in the markets are twenty-pence a piece.

The following account of the gannets in the isle of St. Kilda is given by Mr. Macan. "The rocks are summer totally covered with the folid geese and other fowls, and appear at a distance like so many mountains covered with snow. The neck of the folid geese, not to mention those of other fowls, are so close, that when one walks between them the hatching fowl's on either side can always take hold of one's clothes; and they will often fit till they are attacked, rather than expose their eggs to the danger of being deforced by the fegulls: at the same time an equal number fly about, and furnish food for their mates that are employed in hatching; and there are, besides, large flocks of barren fowls of the different tribes that frequent the rocks of St. Kilda.

"The folid geese, equal almost the same ones in size. The common amement of the herring-fishers shows the great strength of this fowl. The fishers fix a herring upon a board, which has a small weight under it to sink it a little below the surface of the sea: the folid geese observing the fish, darts upon it perpendicularly; and with so much force, that he runs his bill irrecoverably through the board, and is taken up directly by the fishers.

The folid geese repair to St. Kilda in the month of March and continue there till after the beginning of November. Before the middle of that month they, and all the other sea-fowls that are fond of this coast, retire much about the same time into some other favourite regions, so that not a single fowl belonging to their element is to be seen about St. Kilda from the beginning of winter down to the middle of February. Before the young folid geese fly off, they are larger than their mothers, and the fat on their breast is sometimes three inches deep. Into what quarter of the world these tribes of wild fowl repair, after winter sets in, whether into the northern ocean, the native country and water-quarters of herrings in general, or into some other region near the sun, or whether they be of the flying kind, who play into the mysteries of natural history, or have conversed much with writers of voyages can bell explain. I shall only pretend to say that these different nations of the feathered kind are taught to chuse the properest habitats and feeding places, and to shun their quarters feasonably by the unerring hand of God.

From the account given above of the multitude of sea-fowls that seek their food on this coast, we may justly conclude that there must be inexhaustible stores of fish there. Let us for a moment confine our attention to the consumption made by a single species of fowls. The folid goole is almost infaerbly voracious; he flies with great force and velocity, torrs all the day with little intermission, and digests his food in a very short time; he disdains to eat anything worse than herring or mackerel, unless it be in a very hungry place, which he takes care to avoid or abandon. We shall take it for granted that there are a hundred thousand of that kind around the rocks of St. Kilda; and this calculation is by far too moderate, as no less than twenty thou-
found of this kind are destroyed every year, including the young ones. We shall suppose, at the same time, that the island geese feast in these seas for about seven months in the year; that each of them destroys five herrings in a day, a subsistence infinitely poor for so greedy a creature, unless it were more than half supported at the expense of other fishes. Here we have 100,000,000 of the fine fish in the world devouring annually by a single species of the St. Kilda sea-fowls, &c.

In concluding this account of the gannet, it is proper to observe that le grand fou of Bassin and Buffon, and great bay of Carterby, an inhabitant of the seas-shores of Florida, is supposed to be the young or at least a variety of pelicanus Bifinus; and that observed by navigators so common on Ascension and pelicanus piseator, a different species.

BASSAWS, or Bona Shark, in Geography, lie on the west coasts of Africa, beginning about west, or to the south of west from Sierra Leone, and running out far to sea in rounds and hollows, so that ships cannot clear them without standing off out of sight of land.

BASSE, or Basse, a town of France, in the department of the North, and chief place of a canton in the district of Lille; ceded by the Spaniards to France by the treaty of Aix-la-Chapelle, in 1660; formerly a place of considerable strength, but dismantled by Louis XIV. It is situated on the Deule, 2 leagues east of Bethune, and 3* south-west of Lille. The place contains 2171, and the canton 11,913 inhabitants; the territory includes 75 kilometres and 11 communes. N. lat. 50° 53', E. long. 3° 0'.

Basse, in Ebdology, the English name of a fish found on some of the British coasts, and named porca laboris. Linn. Syst. 482. ed. 12.

Basse-Cour, in Building, a court separated from the principal one, and destined for the stables, coach-houses, and liverieservants.

Basse-Cour of a country-seat, is the yard or place where the cattle, fowls, &c. are kept.

That where strange creatures of divers forts are kept for curiosity, is called by the French menagerie. The Romans gave the name of vivarium to that place, where beasts were kept for the public shows.

Basse-Flute is a term used in Middle Age Writers, denotes a collar for cart-horses, made of flags. Hence also the round matted cushions of flags, used for kneeling in churches, are called bafle; in Kent, a truf.

Basse de Flute trompeuse, Fr. in Mefte, a side-flute, a fifth below the usual compass of the German flute, now out of use in France; and we never remember its use in England.

Basse-Flute. When, at the beginning of the 18th century, the flute à-bec, or common flute, was in general use and favour, there were flutes of every size and pitch. F natural being the best in tune, and the e flat key on the common flute, all fongs and other favourite airs were transposed for the flute into that key, or into G natural, at the bottom of the plate, when printed. The bafe flute was an octave below this F, and the e' octave flute an octave higher. See FLUTE.

Basse Téniqua, the base of the key-note, or Tartini's third found, produced by the concurrence of two treble notes perfectly in tune, and readily sustained with two voices, violin, flutes, hautbois, or by two trios in double fops on one violin, or two keys on the organ. See Terza Suona.

BASSEEN, or Basain, in Geography, a fortified city, situated on the point of the continent on the western coast of the peninsula of India, opposite to the north end of Salsette. It lies in N. lat. 19° 15', and under the same meridian as Bombay. This place fell into the hands of the English, after a smart siege in 1780, but was restored to the Mahattas, together with all the other conquests made on that side of India, at the peace of 1783; Salsette and the small islands excepted.

BASSENO, a river of Italy, in the kingdom of Naples, which runs into the Strait, near Cozenza.

BASERSTORF, a town of Switzerland, in the canton of Zurich, 4 miles N. E. of Zurich.

BASSET, or Bassette, a game with cards, said to have been invented by a noble Venetian; for which he was banished. It was first introduced into France, by Sigismondo Juliiianini, ambassador of Venice in 1674. Severe laws were made against it by Louis XIV.; to elude which they disguised the buffet under the name of poor & contre, that is, for and against, which occasioned new arrests and prohibitions of parliament. The parties concerned in it are, a dealer or banker, his assistant, who supervises the losing cards, and the punter, or any one who plays against the banker.

Besides these, there are other terms used in this game: 1. The joffe, or faire, which is the first card turned up by the tailleur belonging to the pack; by which he gains half the value of the money laid down on every card of that fort by the punters. 2. The couth, or slant money which every punter puts on each card; each person that plays having a book of thirteen several cards before him, on which he may lay his money, more or less, at discretion. 3. The pail always, which is, when a punter having won the first flute, and having a mind to pursue his good fortune, crooks the corner of his card, and lets his prize lie, aiming at a sept et le va. 5. The moa, when having won the first flute, the punter is willing to venture more money on the same card. 5. The pay, when the punter having won the first flute, be it a pliulling, half crown, guinea, or whatever he laid down on his card, and not caring to hazard the paroli, leaves off, or goes the pay; in which case, if the card turn up wrong, he looses nothing, having won the couch before; whereas, if it turn right, he by this adventure wins double the money flaked. 6. The alpico, much the same with paroli, and used when a couch is won by turning up, or crooking the corner of the winning card. 7. Sept et le va, the first great chance or prize, when the punter having won the couch, makes a paroli, and goes on to a second chance; so if his winning card turns up again, it comes to sept et le va, which is seven times as much as he laid down on his card. 8. Quinze et le va, is the next higher prize, when the punter, having won the former, is resolved to push his fortune, and lay his money a second time on the same card, by crooking another corner; in which case, if it come up, he wins fifteen times the money he laid down. 9. Trent et le va, is the next higher prize, when the punter crooking the fourth corner of his winning card, if it turn up, wins thirty-three times the money he first flaked. 10. Soixante et le va, is the highest prize, and entitles the winner to sixty-seven times his money; which, if it were considerable, flanks a chance to break the bank; but the bank flands many chances first of breaking the punter. This cannot be won, but by the tailleur's dealing the cards over again.

The rules of the game of buffet are as follow: The banker holds a pack of fifty-two cards, and having shuffled them, he turns the whole pack at once, so as to discover the last card; after which he lays down all the cards by couples. The punter has his book of thirteen cards in his hand, from the king to the ace; out of these he takes one card or more at pleasure, upon which he lays a flake. The punter may, at his choice, either lay down his flake before the pack is turned, or immediately after it is turned, or after any number of couples are down. Supposing the punter to lay down his flake
BAS

Lake after the pack is turned, and calling 1, 2, 3, 4, 5, &c., the places of those cards which follow the card in view, either immediately after the pack is turned, or after any number of couples are drawn. Then if the card, upon which the punter has laid a lake, comes out in any odd place except the first, he wins his stake. If the card which the punter has laid a lake, comes out in any even place except the second, he losses his stake. If the card of the punter comes out in the third place, he neither wins nor loses, but takes his own stake again. If the card of the punter comes out in the second place, he does not lose his whole stake, but only one half; and this is the case in which the punter is said to be faced. When the punter chooses to come in after any number of couples are drawn, if his card happens to be but once in the pack, and is the last of all, there is an exception from the general rule; for though it comes out in an odd place, which should entitle him to win a stake equal to his own, yet he neither wins nor loses, from that circumstance, but takes back his own stake.

This game has been the subject of mathematical calculations. Mr. De Moivre solves this problem; to estimate at buffet the loss of the punter under any circumstances of cards remaining in the pack; when he lays his stake, and of any number of times that his card is repeated in the pack. From this solution he has formed a table, shewing the several losses of the punter in whatsover circumstances he may happen to be. See Doctrine of Chances, p. 63.

From this table it appears, 1. That the fewer the cards are in the pack, the greater is the loss of the punter. 2. That the least loss of the punter, under the same circumstances of cards remaining in the pack, is when his card is but twice in it; the next greatest when but three times; till greater when four times; and the greatest when but once. The gain of the banker upon all the money adventured at buffet is 15% 3d. per cent. De Moivre, Doct. of Chances, p. 69, edit. 3.

Basset, in Zoology, the name given by Buffon to that kind of dog which is called in England the turnspit, conis vortigens of Gmelin. Of this kind he makes two varieties; le basset à jambe droites, and le basset à jambes tortes; the first having straight legs, and the last crooked ones.

Bassetterre, in Geography, a general name given by the French to the low lands of the West India islands; such are the S.W. part of the two parts of Guadaloupe island, separated by a small arm of the sea, called the Salt river: and also the N.W. part of the island of Martinico.

Bassesterre Town, a sea-port town on the S.W. coast of the island of St. Christopher in the West Indies, and capital of the island, situated at the mouth of a river, opening into a bay, called Basseterre road. The town contains about 800 houses, and is defended by three batteries. N. lat. 17° 24’. W. long. 61° 37’.

Bassesterre Town is also a sea-port town on the S.W. coast of the island of Guadaloupe, regularly built, with some handiwork houses, and defended by a citadel. N. lat. 15° 59’ 30”. W. long. 61° 59’ 15’.

Basetting, in the Coal Mines, denotes the rise of the vein or coal towards the surface of the earth, till it come within two or three feet of the surface itself. This is also called by the workmen creeping, and stands opposed to dipping, which is the descent of the vein to such a depth that it is only, if ever, followed to the coal.

Bass, Angelo, in Biography. See Poliziano.

Bass, Laura, an Italian lady, distinguished by her acquirements, was the wife of Dr. Joseph Verati of Bologna. She understood the Greek, Latin, and French languages, as well as her own, and was eminent for her literatures and science. In 1732, she was honoured with the doctorial dignity, and she kept up a correspondence with many learned persons in Europe, who admired her talents and accomplishments. She commenced a course of lectures in philosophy in 1745, and continued the same till her death. Her morals were pure, and her character amiable; and she was liberal in her charity to the poor and orphans. She died at an advanced age at Bologna in 1758. N. All. Dict. B. 9.

Eff. Ch. Col. four-leaved; Cor. eight-cleft; tube inflated. Stam. 16; drupe five-feathered. (Berry five-celled, with a seed in each cell. G.)

Species, 1. B. longifolia. Thalippe Malabaridas, and Mule Ceylonensis. "Leaves ovate-lanceolate, peduncles axillary." A lofty tree, with the utmost branches recurved, thickish, and covered with a grey down: leaves on them alternate, approximating, petioled, entire, veined, naked, half a foot long, and deciduous; petioles roundish, short; peduncles axillary, from one to five, filiform, one-flowered, upright; after flowering, prolonged and pendulous; berry oblong, slightly compressed, smooth, shining, and yellow, with a white band. A native of Malabar and Ceylon. 2. B. dubia. Seed large, half-moon shaped; flattened like a lens, smooth and shining, of a dark chestnut colour, excepting an oblong, ragged, umbilical area, which is almost white. The shell is thick, lumpy, and very hard. The feeds of basia are not easily distinguished from those of sapota, without attending to the albumen, of which basia is entirely delunate; and the inner integument is also commonly wanting. 3. B. obovata. Forst. Flora. n. 200. "Leaves obovate; peduncles heaped, terminating." A native of the isle of Tana, in the South seas. Martyn’s Miller’s Dict.

Bassiano, Laura, in Biography, born at Placentia, discovering early a propensity to the knowledge of medicine, was sent to Padua, where she studied under Baptifl Moni, and, having performed the usual exercises, in 1544 he was admitted doctor in philosophy and physic. In 1545 he was made professor in those sciences, and acquired considerable reputation as a public teacher. Going to his house, in 1562, he was assassinated by an assassin, who killed him by stabbing him in several parts of his body with a bayonet. He left several publications, of which the principal are, "Intrologia five dialogi duo, in quibus de universae artis medicinae, praeque vero morborum omnium et cognoscendorum et curandorum absolutum libri, in duo volumina divisi," Belliæ 1543, 410; "De origine et causa pellis," Patav. 1555, 8vo; "De prodigiosis parturit" Haller. Bib. Med. Ely. Dict. Hii.

Bassiano’s River, in Geography, is situated on the coast of Labrador, in North America, near opposite to the north point of Newfoundland.

Bassing, a town of France, in the department of the Meurte, and chief place of a canton in the district of Dieuze, 14 league N. E. of Dieuze.

Vol. III.

5 D

Bassius,
BASSO.

BASSIIUS, Henry, in Biography, son of Gerard Bassign, or Balsa, a surgeon of eminence at Bremen, born 1690. In 1713, he went to Halle, where he studied medicine under Frederic H. F. B. (1713 to Strasbourg, and two years after to Balsa; attaching himself particularly to acquiring a knowledge of the improvements that had been lately made in anatomy and surgery. Returning thence to Halle, he was created doctor in medicine: and soon after professor in anatomy and surgery, which office he continued to hold till the time of his death, March 9th 1734. His works are: "Difputatio de filia aut felicitat curanda," 8vo. 1718; "Observations anatomiae chirurgico-medicas," Halle 1731, with figures, representing some instruments invented by the author,—a work much commended by Haller; "Tractatus de morbis venereis," Lipsiæ 1704, 8vo; a polhumous work, to which the editor has added some valuable observations. He also published, in the German language, "Commentaries on Nuck's Art of Surgery," 8vo. 1728. Haller, Bib. Anat. et Chir. Eloy. Diet. Hist.

BASSO Continuo in Music, originally meant the accompaniment to the higher parts of a sonata, concerto, or chorus, in whatever clave it was written, which served as a base, when the real base was silent; as in fugues, and other movements; to let the accompanist on the organ or harpsichord know what was doing by the other instruments, while his part was at rest. This may full be seen in the organ part (organum) to Corelli's Sonatas, Op. 11, which were composed in the seventeenth century, after which the custom was discontinued, there being no influence of it in his other works. Though in the sonatas of Bassign, his master, and in those of Corelli, it is constant. Handel, in his hautbois concertos, and in his twelve grand concertos, calls the ripieno base, basso continuo.

It was to this kind of choral base for the organ or harpsichord, in ecclesiastical music, that the harmony of the whole piece, without a treble part, was first expressed by figures over the base notes. Basso continuo, by an awkward translation, is, in English, synonymous with thorough-bass, which fee.

It was in the beginning of the seventeenth century that Ludovico Viadana (not Viana, as erroneously written by Rouneau, and copied from him in both editions of the Encyclopedia) one of the most distinguished ecclesiastical composers of that time, invented the indication of chords by figures, in what the Italians call the basso continuo, and the English thorough-bass, or accompaniment on keyed instruments, harps, harpsichord, and in recitatives, even vocalcellos; but we have found several instances of the minute beginnings of this expedient before the time of Viadana; though he was doubtless the first who drew up general rules for expressing harmony by figures over the base in 1615. Dravudius, in an ampler list of his ecclesiastical compositions, which were very numerous, tells us of one that authenticates his claim to this invention, which was a collection of all his choral pieces of one, two, three, and four parts; "with a continued and general base, adapted to the organ according to a new invention, and useful for every finger as well as organist; to which are added short rules and explanations for accompanying a general base, according to the new method." Viadana was therefore the first who composed an organ-base different from the voice part, in the execution of which the new-invented figures enabled the performer to give the fingers the whole harmony of the several parts of a full composition, without seeing the score.

In 1731, Mattheyon, in his "Grundlage der gesetzlichen organischen Schule," a treatise on thorough-bass, has given a list of twenty-two writers on accompaniment from the time of its invention in 1606. The invention has been indisputably ascribed to Viadana in Draudius's Catal. ii. (Draudius Bibliotheca Classica, 2 vols. 4to. Frankforti 1625), where there is a list of all his works, and among the rest, "Dr. Ludovico Viadana Itali opera omnia faciemur concertationum, 1, 2, 3, 4. voc. cum basso continuo & generali, organo applicato novaque inventione pro omni genere et forte cantorum et organorum accommodata. Adjuncta infusor in basso generali hujus novae inventionis instructio et succincta explicatione, Latine, Ital. et German. op. Steunum 4. 104."

In the list which Mattheyon has given of twenty-two authors on accompaniment before 1731, it is observable that only one treat is in English; and that written by Kelller a German, who lived in Queen Anne's time, and dedicated to her majesty six sonatas for two flutes and a basset horn.

In Rameau's system, and still left in that of the abbe Feyton, as the fundamental base can have no melody, but what arises from its own harmony or single common chord, la balle continue may be regarded as a kind of low treble under the violins and tenor, or as a variation of the fundamental base.

BASSO Stretto, Ital. a base confined to a few bars or notes, repeated to different and varied treble parts. The English call this kind of monotonous movement a ground. During the seventeenth century, the Italians and their imitators were very fond of writing upon a ground-bass; Stradella and Purcell frequently manifested their ingenuity under such restrictions; nor had the fashion quite finished in Handel's time, as may be seen in the last chorus of his Dettingen Te Deum, and elsewhere in his numerous and admirable works.

BASSO Cantus, Ital. Basso. Fr. the vocal base-part, or the vocal base in an oratorio, opera, or concert.

BASSO RELIEVO, Italian, Bas-relief. French, in Sculpture, is the representation of figures on a back ground, in such a manner that no part of them is detached from it; alto-relief, high relief, has the greater parts attached to the back ground, whilst the smaller parts are free from it; some diffusing a third kind, or mezzo relievo, middle relief, between both; although it must be acknowledged that all three kinds are implied, in a general mode of speaking, by the common term of basso-relievo, or bas-relief, because almost all figures in relievo, even alto-relievo, are more compressed or flattened than their insulated archetypes in nature. This, like many other terms in the art of design, is of modern date, and was most likely invented, or at least compounded and applied, in the eleventh or twelfth centuries, when sculpture and architecture began to revive in Italy, and these kinds of works became a very considerable decoration to the new cathedrals. The Greeks, to whom we must look for the first definitions in this art, as well as the most excellent works, called this species simply anaglypta, carved (Pliny, lib. 33. c. 11.) that which we call alto-relievo was disfigured by them from the low-relievo, by the word, tortucienes, rounded. Pliny, l. 34. c. 8.

Basso-relievo, although a considerable province of sculpture, is in a particular manner allied to architecture and under its dominion; as any considerable work of this kind must be made for the pediment, frieze, or pannel of a building, or architectural form, such as a facadophagus or pedestal: and therefore the general shape of the ground, the distribution and projection of the figures, must be subervient to the surrounding and containing parts, in order that they may produce a beautiful whole.

It is well remarked by the authors of the French Encyclopedie, that "the origin of basse-relievo is confounded with that of the hieroglyphic; that is to say, it owes its birth
birth to figured writing. Under this point of view, it is common to all people, and is found among the most savage. It was invented by necessity, appropriated by religion. The progres alone of the arts of imitation could perfect their primitive signs and give them life. This honour was reserved for the Greeks. In Greece the arts were in some furt the miniatures of religion; in Egypt and Assy they were the figures. A religious respect for their primitive characters, which worship had sanctified, feared perhaps to change the ideas in changing the forms to which they were attached: all contributed, among the Egyptians, to retain the arts in a kind of infancy, from which religion prevented them from emerging.

All the larger hieroglyphics engraved in the surface of Egyptian architecture, or on the figures of men and inferior animals, may be considered as baffle-reliefs; and of the most simple, it may be consequent of the most ancient kind; because the figure was sunk in such a manner, that the surface of the ground was left, forming an outline or outline whose greatest depth was equal to the greatest projection of the figure, which was productive of these advantages. As many of the hieroglyphics were cut in granite, a very brittle marble, it prevented the danger of spoiling the outline in sinking the back-ground, one third of the labour was saved, and a strong shadow all round the figure, particularly when the sun shone on it, defined its form to the first. All the temples and palaces enumerated by Rippaud, and described by Denon in the late expedition of the French into Egypt, showed that the greater part of those edifices, as well as interior works, were covered with hieroglyphics, or sacred figure-writing in the kind of bas-relief above described: the largest of these formed regular ornaments to the friezes, centres over the doors, corresponding tablets, or pannels where the symmetry of the architecture required. The principal of these figures, according to a comparison of what we find in Orus Apollo, submitted on Hieroglyphics, and other authors, with the hieroglyphics themselves, seem to be the representation of some characteristic or attribute of the divinity, and the operations of his providence in nature, accompanied by acts of adoration; the inferior figures and characters are ranged in lines like writing.

Besides the hieroglyphics, the Egyptians employed bas-relief, with the ground levelled to the I well part of the figure, to describe the political or military prowess of their heroes, and for other historical purposes. Of this kind are those in the palace of Karnac, engraved by Denon, and those described in the Bird's Well, of which there is a description in the hall of the British Museum. It is in a soft calcareous stone in very low relief: the subject, men laying oxen. The human figures are in violent action, which they seem to have attempted in historical more than in sacred subjects. Nor is it surprising that such actions are extravagant, and not well rendered; when we see by the works themselves, that the stock of knowledge which the sculptors possessed, was insufficient to account for the parts of the body by a fine proportion, beautiful outline, and the anatomical changes of appearance in the different circumstances of motion. But the prodigious quantity of this kind of labour still remaining must have occupied the diligence of so many hands for a series of ages, that they could have had little leisure to make advances, either in the sentiment or scientific perfection of the figures. This may account, in part at least, for the execution of the quadruped being better than that of the human figure, which is so much more difficult.

It is necessary to give a general account of the character and style of design in the Egyptian figures, because what is said on this subject will be in a great measure applicable to the early progress of the arts among the Hindoos, Persians, and Greeks, allowing for some peculiarities in each nation. The arts of design are chiefly imitative in the early attempts; and we find in the Egyptian figures, compounded of different animals, that each part is a copy of nature. In the human figure, the body and limbs were represented in general forms. The face, as being the most interesting part of the person, was more minutly expressed. The hair was composed of the pointed egg, lines of the eye-brows and lips, simple curves inclining upwards from the nose, the bottom of the nose, and the line of the mouth inclined upwards in the same direction with the eyes. The eyes were full, nearly on a level with the forehead and cheeks, and the lines of the eye-brows, lids, and borders of the lips, marked with precision. The cheek appeared small and bony, the neck round the shoulders high and broad, except the marking of the breast. Little distinction of the muscular forms in many parts of the body and limbs, the loins narrow, the limbs round, rather straight and slender, their joints slightly indicated, the hands and feet rather flat, the fingers and toes rounded, without the appearance of joints, and nearly of the same length. According to a figure Denon found, measured by 22 figures in length, the half of the figure each way was from the division of the thighs, the head was rather less than a seventh part of the figure's height. See Denon's Voyage, plate 124, fig. 1.

The quadrupeds on Egyptian monuments, are represented in profile, and in the simplest attitudes. The parts of which those are composed, are fewer and more general than those in the human figure. This is one reason why the Egyptians excelled in their animals; the mechanical manner in which the shoulder is drawn of the lion and sphinx (where they have displayed more anatomy than in any other part) presents a simple, but just, account of the structure of that member of the body: these evolutions apply to the rate of sculpture before the time of Alexander the Great: after which period, it partook of the improvements introduced by its Greek conquerors.

Baffle-reliefs are found in India, which decorate the excavations of Ellora and Elephants in an astonishing perfection. The subject is faceted, suitable to the temples in which they are carved; the drawing of the figures and their parts bears a strong resemblance to the Egyptian style; but inferior in this, that many of the figures have very large heads, the limbs and bodies disproportions. It seems likely that the Egyptian hieroglyphics are more ancient, because more simple than the Hindoo baffle-relief; the former having the ground left even with the highest relief, the latter having the ground cut level with the lowest outline of the figure. For the most extant, accurate, and valuable publications of these subjects we are indebted to the abilities and unceasing labour of our countryman Thomas Daniel, Esq. R. A. The Persians employed baffle-relief like the other ancient nations as a figured writing, at once to record and represent the symbols of Almighty power and operation, their religious ceremonies, and the prowess of their heroes. The bas-reliefs on the palace of Persepolis and the royal tombs are arranged in lines, horizontal and perpendicular, to answer the double purpose of description and architectural decoration: the style of drawing resembles that of the figures in the later hieroglyphics, although the dreffes are extremely different. The Egyptians are particularly distinguished by the headdress, the mitre, the full hair artificially curled, the close tunic, the apron of papyrus; the Hindoos by the necklace, bracelets, and anklets; the Persians have long beards and hair ending in small curls, caps, full tunics with regular folds and large sleeves; the Medes in the same ruins of Persepolis have close tunics. The drapery in these bas-reliefs is rather...
more like nature than that in the Egyptian hieroglyphics and other bas-reliefs, but this may be the consequence of what the artists had more frequently to imitate. Indeed of a proof that the Minoans were more advanced in Peru than in Egypt, which seems still less probable when we consider, the different portions of the human figure, the variety and extent of the historical compositions in the palace of Karnak, the Theban tombs, &c. and the exquisitely neat and perfect execution of the hieroglyphics on the obelisk of Sebennix, lately erected on Monte Citario by Pius the Vth. far exceeding the workmanship of any figure at Persepolis. See Donen's Egypt. Le Brun's Travels, vol. 2.

The earliest Greek sculpture is still more like the Egyptian in the principles of design, rather than that of any other nation. The face of the human figure has the same oval, the features defined by the same simple curves, the eye kept full as the caifull to execute, being more distinguished by the lines of which it is formed, than by its appearance in profile; and nearly the same general parts represented the body and limbs. That there should be this similarity in different nations in the imitative arts, is strictly agreeable to reason; because conformably to their limited progress in science, they will represent in a simple and grofs manner those objects, the detail of which their minds have neither comprehended nor understood, and which in that stage of progress the hand would be as little likely to perform with the requisite accuracy. It is equally reafonsable to expeach imitations should reemblé each other; being made from examples of general likeness, and done without the influence of manner, which is the consequence of imitating art instead of nature.

It is most likely that some imitations in sculpture of the human figure were made in Greece, previous to the introduction of letters by Cadmus, because modern travellers have found such imitations among many barbarous people unacquainted with letter-writing, and because the Greeks appear to have used figure-writing before they were acquainted with letters: see Wolff's Prolongemena to Homer, page 81; who believes that figure writing only was known in the time of Homer. But it is equally certain that small bronze figures exist with inscriptions of Cadmean letters on them, which are very poor and barbarous imitations of the human form; so that we may fairly infer, that the sculpture previous to this period could not have been very superior to the productions of Mexico, Othoehie, or the Sandwich Islands. In the popular story of the Maid of Corinth, related by Pliny, lib. 35. cap. 12. he says, Dibutades the Sicilian potter, her father, first invented a method of taking likenesses, the procefs of which is described as follows: "His daughter being in love with a young man who was going to a foreign country, the circumfered the shadow of his face with lines upon the wall by lamplght; her father took the impression in clay and baked it in the fire with his vaves." It seems, therefore, that as this was the first invention of portraits in clay, and as this portrait was only the relief impressed from a line scratched on the wall, that it must have been the very first image of baflo-relief. Pliny proceeding fays, that Dibutades made another addition to baflo-relief, by ornamenting the lowest row of rounded tiles, used to terminate roofs, with male faces. These may be considered as two inventions, which distinguished the Sicilian school. Pliny does not say at what time Dibutadés lived, but he mentions him before Demaratus the father of Tarquinius Priscus, who must have been 600 years before Christ.

Independently of what may be deduced from these quotations, concerning the progress of baflo-relief in Greece, examples in this branch of sculpture exist in marble and bronze, which, with the aid of coinz and gems, if properly arranged, would form a complete chronological series from the introduction of letters in Greece. As the most ancient subjects to be chiefly depicted are those which bear inscriptions, this arrangement would necessarily follow: the inscriptions of Cadmean letters first, the Bouleuthedon manner of writing next, and the more modern as circumstances point out their propriety. This method would be found perfectly agreeable to the progress of science discernible in the works themselves, as well as the perfection of execution; and thus the antiquarian, or the artist having incurred an accumulation of testimony, would be in little danger of mistake. A passage in Paulinus, the first Epict, or 6th book, shews the propriety of this method: he says, the cedar chief in which Cyphalus was preferred by his mother (about 690 years before Christ), was denoted by his politerity in Olympus. This chief is described as being covered with baflo-relief of allegorical and heroical subjects, explained by Bouleuthedon writing, which the author describes as very old and difficult to read.

The earliest Greek sculpture which has come down to us is equal in the proportion of the figure to the Egyptian, and superior in the drawing of the body and limbs. Vitruvius informs us, that as the height of the human figure was six times the length of the foot, that was made the rule for the Doric column. (Book iv.) Thus we see the Greeks had been in the habit of measuring the human figure by its own parts, previous to the establishment of architectural proportions; and we find very tolerable general forms of the muscles and bones most commonly seen in the living body, which those early Greeks copied by close attention to the naked figures they constantly saw before them, without the aid of anatomical fylens: for Pliny (lib. xxix. c. 1.) says, the art of medicine remained in the darkest night from the siege of Troy to the time of Hippocrates. A few examples from the many existing will shew the progress of sculpture in baflo-relief, from the introduction of letters in Greece to the time of Phidias: these shall be set down according to their apparent antiquity, and followed by general observations.

In Winkelman's "Monumenti inediti," plate 3. 1s a print from a fcarabæus of Jupiter in his car, holding the thunder with one hand, and trident with the other. This has the appearance of great antiquity in design and character, and perhaps is the oldest work cited in this article. The next is a patera of bronze in the British Museum, on which is vividly carved Minerva, subduing Hercules, or wisdom prevailing over strength. The next is an engraving of live of the seven chiefs who besieged Thebes. The left is Hercules bearing away the tripod from Apollo, which, by the improved vyle of drawing, seems to approach the time of Phidias. The first observation that occurs in this part of the subject is, that antiquarians have fallen into a considerable mistake in pronouncing many early works to be Etruscan, which later discoveries have almost certified to be Greek. The Etruscan subjéts cut on gems, the backs of which were formed into scarabæi like the Egyptian seals, have been positively called Etruscan by Winkelman; notwithstanding that the style of the figures is early Greek, the subjécts are Greek, and the letters upon them are Greek; besides which, Mr. Hawkins, a late accurate and highly qualified traveller, has brought a Cornelian fcarabæus found in that country to England, which has a Mercury engraved on it in that early style called Etruscan. How many more of these might travellers, if they sought for them, find in that country? And is it not likely that the Roman lords of the world would bring into their own country as many curious Greek gems as statues, when a dozen of the former may be conveyed in the palm
palm of a man's hand, whereas vest operations are necessary to transport only one mable or bronze statue? These arguments are sufficient to account for the gems of this description which have been found in Italy; besides some which may have been wrought in that country by Greek colonists, or the scholars of Greeks. A crowd of evidences might be produced, which would show the Greeks, that the vase, falsely called Etruscan, have been found in great abundance in Greece. Mr. Stuart and Mr. Parris brought fragments of them from Athens, which are lodged in the British Museum; Mr. Greenes brought several entire and beautiful painted vases from Greece, some of which were afterwards in the possession of Sir William Hamilton; and to these might be added many other testimonies and collections on this part of the subject.

One error more should be related before we proceed: Winkelmann (vol. i. pp. 5, 6, c. 4.), in his history of the art, affirms, that the Etrusans gave their Fauns horsetails; whereas the Greeks represented Fauns and Satyrs with short tails like goats. The head-piece, (p. 23, chap. 7, vol. i.) of "Stuart's Athens," is a sufficient answer: it is a bas-relief of a Bacchanalian dance, in which two Satyrs have horsetails. It was found in the ruins of the theatre of Baccus, is of the style commonly called Etruscan; but in fact, according to the time when this theatre was built (nearly 500 years before Christ), it is of the style of sculpture which prevailed in Greece immediately prior to the time of Phidias.

The general remarks on these works, during the period of about 500 years from the time of Cæmus to the time of Phidias, shall be confined to the three following: the manner of representing the gods; the manner of drawing the human figure and its actions; and, lastly, some observations on the draperies and utensils.

From the two proofs adduced that Grecian sculpture has been called Etruscan from the want of sufficient knowledge of the subject, and to which other proofs equally certain might be added (for instance that all the early Greek coins are of the same style with that called Etruscan), it will seem to be a safe conclusion, that all ancient sculpture representing Greek subjects, should be considered as the work of Greeks, their colonists, or scholars, excepting in such cases as there is sufficient reason to believe the contrary.—Conformably to this regulation, the following observations may be offered on Greek sculpture preceding the time of Phidias. As the ancients represented their divinities in human forms, in the early times those forms were gross and imperfect, their aim being only to copy human nature; thus, in the gem above cited, of Jupiter with the thunder and trident, in Winkelmann's "Monumenti inediti," pl. 3, his body and limbs are formed of few parts, gross and elegant, his face is beardless, and his hair is thick and matted. Nearly the same may be said of the Hercules on the bronze patera in the British Museum above mentioned; a figure of Neptune on the oldest coins of Paestum; and the other monuments of the same ages, which represent Jupiter, Neptune, Mercury, and Hercules, by such figures as they employed to represent common men, equally devoid of beauty and character. The face of Minerva is not more delicate than that of Hercules, nor do his hands appear more robust than those of Apollo. The gem in only known by their round heads; Jupiter by his thunder, Neptune by his trident, Mercury by his caduceus, Minerva by her helmet andegis, &c. The gem of Jupiter with the thunder and trident above mentioned, which has also a four-footed animal under his car, perhaps a horse, agrees with Orpheus's hymn to that god, in which earth and sea are said to be his; in this respect agreeable to the most ancient religion, and an argument of the high antiquity of the workmanship.

Concerning the manner of drawing the figure, it has been judiciously observed by the authors of the French Encyclopaedia, that the Greeks began where the Egyptians left off, and some of the best works of the Egyptians, the vase (the bod) of the Egyptian figures, are nearly the dimenisions of the beginnings of Grecian art. However, improvements were soon made; they began to distinguish between muscles and bone, and the surface of the body; and limbs were carefully marked with their greater sinewations; the abundant muscles and gullet marked the neck, the collar bones were marked by nearly straight ridges, the edges of the ribs by an high arch, the abdomen by a double row of three nearly-square muscles on each side of the linea alba, and the division of the trunk from the limbs is strongly indicated by the edge of the pelvis; the forehead is rounded, the biceps of the arm defined, the elbow expressed; a gentle indentation down the back of the lower arm showed the situation of the ulna, the arm tapered downwards with a graceful swell for the muscles, and blankets for the part composed of bones and tendons; the inbides of the thighs were flattened in the progress of the factorius muscles, the lower tubercle of the thigh bone was drawn immediately above the knee, which was expressed by the form of the patella; the inbide of the shin was strongly expressed, as were the calves of the legs; the ankles were near and small, rounded at the bottom; the feet and hands partake more of the forms of nature than the Egyptian, and the fingers and toes were made more neat, distinct and various in the outline; on the back, the blade-bones were marked as being little disfigured by flesh, and the glutea as small and firm. Upon the whole, there are men in an early state of society, whole hard and constant exercise in leaping, running, feats of dexterity in war and hunting, has made the covering of their bones tenuious and elastic, tapered their limbs, and these quick and strong digestion has kept the loins narrow and the abdomen flat, whilst a free and powerful respiration expanded and raised the chest. The first essay of sculpture in the round figure, required that the arms should be attached to the body, and the legs joined together, for support, and to prevent the insipid artist from breaking his work: but this restraint did not extend to bas-relief, in the same early compositions of this kind, in which you see such simple positions as approach to formality. There are also figures in violent actions; as dancing fauns, groups contending, and such exertions as shew the figures with sprawling, angular, and extravagant appearances; for hitherto the indications of grace were as small as those of beauty.

The draperies in the early bas-reliefs are thin, shoewing the forms of the body and limbs; the folds regular, small, and distinct, confiding chiefly of perpendiculars and zigzags. Some of the head-dresses consist of small curls, very like the fashions of barbarous nations described and drawn by modern travelers; and in the bronze patera in the British Museum above mentioned, the club of Hercules is ornamented with spiral flutes, like one brought by Captain Cook from the Sandwich islands.

The bas-relief of Hercules bearing the tripod from Apollo, mentioned above, forms a nearer time of Phidias than any of the other above examples; not only from the superior elegance of the design, but likewise from its being in style very similar to the Bacchusian dance found in the theatre of Baccus at Athens. This subject of Hercules bearing the tripod from Apollo, is described by Pausanias in...
in the temple of Apollo at Delphi. It has been frequently repeated by the ancients in bas-reliefs and gems. A bas-relief of this subject, brought from Greece, was preferred in the Museum Nani at Venice; besides two others in the Alban collection. Thus we ascertain this to be a Cretan work, although in a style which has been supposed Etruscan; and by the likeness of its manner to the Bacchanalian dance above mentioned, its age may be nearly ascertained.

Our subject now presents the most important and perfect period in the art of sculpture, beginning with the great works executed by Phidias and under his direction. During the administration of Pericles, Greece enjoyed physical advantages, as well as moral and political institutions, peculiarly adapted to give the arts of design that perfection which could not be looked for in other countries. The climate was temperate, warm, and genial, which, to penetrating and elevated genius, added beauteous perfections in its inhabitants; their games and exercises gave vigour and perfection to their forms; which initiated and familiarized the spectator with all the appearance of beauty in the human figure, in the different states of exertion or repose, whether naked or clothed. The practice of the arts of design was the peculiar privilege of those who possed the greatest natural advantages, and were the belit instructed; and in the person of the artist, as well as the subject represented, were frequently united the philosopher, the lawyer, and the heroic defender of his country. Such were the studies for the artists, and such were the men who practiced the art. The fiores of theological and metaphysical knowledge had been laid in from Egypt and the East; science had accumulated; and commerce cultivation, and patriotism, supplied the means of raising those monuments which were to be the admiration and study of all future ages.

There were the times and circumstances in which Phidias was employed by Pericles to adorn Athens with architecture and sculpture, with the assistance of the architects Callistrates and Ictinus, who worked under his direction. Under these illustrious men, the Propylæum, the Temple of Minerva or the Parthenon, in the citadel, and the Temple of Theseus in Athens, were erected. The decorations of sculpture in these buildings are the most perfect specimens of art; which we must apply ourselves to, with the utmost diligence to understand, if we would entertain hopes of producing any thing excellent in the same kind. The baso-reliefs which fill the friezes which go round the pronaoe, cell, and portico, of the Parthenon, represent the panathenæum procession in honour of Minerva; which consists of a numerous company on horseback, victors in chariots, men leading oxen to sacrifice, tray-bearers, choruses of virgins, some bearing candletsicks and some baskets, with their attendants and attendants. The sacred veil is produced and examined, the hierophantes explain the mysteries, and the gods themselves are seated, holding, directing, and approving the whole. The alto-relievo in the metopes are the contelli of the Lapiths and the Centaurs. The alto-relievo in the tympanums of the cell and cell ends, are, alas! no more; war has deprived us of them. That of the cell end was a miracle of art, from the remaining fragments (see Stuart's Athens, vol. ii.); and such it appeared to Sir G. Wheeler, who had the happiness to see it entire. However, we know by Sir George's description and drawings, that the subject of the cell end was the birth of Minerva, or rather Minerva introduced by Juno to the gods; that on the cell end, the contelli of Minerva and Neptune for the patronage of Athens. As these subjects are of the highest kind the mind can conceive, so they are the noblest the hand can execute: they are theological and moral, as they represent the gods, their operations in the government of the universe, and providence in the disposition of human affairs; the heroes are exerted in the cause of justice, and the destruction of monsters.

Mr. Fuseli, the able and learned professor of painting in the Royal Academy of London, has judiciously applied Aristotle's division of poetry to the arts of design; and he considers the great productions, as either epic, dramatic, or historic. According to these claffes, the sculpture in each tympanum was entirely epic, as the gods only were represented in them engaged in single acts; the groups in the metopes are dramatic, because they represent a series of actions; and the frieze which goes round the temple is epic, as much as the gods are predomine; and are perhaps also historic, as particular persons and events may be represented in the procession. In the temple of Theseus, the alto-relieves formerly in the pediments are gone entirely; nor do we know even what the subjects were. In the frieze round the pronaoe is the battle of Marathon, in which the appearance of Theseus casts great honours on the Periæus; Jupiter, Juno, and Minerva, Neptune, Apollo, and Diana, sit, behold, and determine the victory, the trophy of which is raised by the Athenians. The battle of the Lapiths and Centaurs is in the frieze of the porticoes: the metopes are filled with the labours of Theseus and Hercules.

The execution of these works is equal to the conception; the sentiment is elevated and fit, the composition is noble, full, and various; the gods are sublime and beautiful, their poëtions present dignity and repose; the heroes are vigorous and active, and an admirable simplicity reigns through the whole; whether you are roused by the terrific engagement of a Centaur and a Lapith, or captivated by the modesty of the virgin choruses. In the battles, the figure is shown in those elastic curves and varied movements, those uncommon but advantageous situations, which equally excite surprise and admiration; every part is intelligible; they occupy such spaces of the ground as leave sufficient blank to render the outline distinct; and their quantities are so distributed, that one part is not bare while another is crowded: the lines themselves also become an ornament. The ifories are told by one plan or ground of figures; and, like the principal characters in the tragedies of Æschylus, Euripides, and Sophocles, their effect is weakened by no underplot of inferior heroes. The drawing of the figures is of the finest style, the outlines and forms are chosen, the greater parts boldly expressed, the lesser parts delicately indicated, but not more than necessary. The heads fine, the drapery rich in folds, but perfectly natural; some of the remaining hands and feet of the most perfect beauty; and the horses may be described in the words Sir George Wheeler used to express his opinion of those he saw in the eastern tympanum of the Parthenon: "The horses are made with such great art that the sculptor seems to have outdone himself, by giving them a more than seeming life; such a vigour is expressed in their prancing and stamping, natural to generous horses." The edges of the figures have been kept square in the working, to give the colder effect to the relief; which was not high in the procession round the frieze under the portico of the Parthenon, in order that the sculpture might not overpower the architectural member. The sculpture in the two pediments of the Parthenon, the metopes in that temple and the temple of Theseus, as well as that round the frieze of the last temple under the portico, are in alto-relievo. This Phidias discovered; it is called tereatien, rounded, by Pliney (lib. 34. cap. 8.); and he says, Polyclitus "so taught tereatien, alto-relieve, rounded work,
work, as Phidias had invented it:—et toreuticae sic crudii,
ut Phidas aperuit.

Belides the basso-relievs above mentioned, several others in Athens are of the highest beauty; the figures on the Temple of the Winds; the story of Bacchus and the Tyrrhenian mariners transformed into dolphins, on the Choragic Monument of Lycurges (Stuart's Athens, vol. i.), raised in the time of Alexander the Great; and two alto relievs of the battle of the Athenians and Amazons, with another battle, subject unknown. (See the last two plates, vol. ii. of Stuart's Athens.)

Before we quit the subject of basso-reliev among the Greeks, it is proper to observe, that foliage ornaments in basso-relievo seem to have been introduced in Ionia about the same time with the Ionic capital; in the reign of Alexander the Great. (See the capital of an Ionic pillar enriched with foliage, in the ruins of the temple of Apollo Didymeus, sub-piece, p. 55. Rivet's Ionia.) These inventions are the two characteristics of the Ionian school.

Soon after this period, the most eminent Grecian sculptors and architects were almost entirely engaged in decorating the capital of their Roman conquerors. Most of their public works at home were inferior in beauty and spirit, in proportion as the intention was debased, which was chiefly that of paying verbose compliments to their masters; and the buildings raised, with a very few exceptions, were distinguished by a colonial inferiority from those of Rome, which the genius of Greece, and the spoils of the world, rendered the most magnificent of the times.

We may begin the observations on the basso-relievos executed or existing in Italy, by some notice of those cut in the rock. In the garden of the Capuchin's convent at Palazzuolo, on the lake of Albano, is a tomb; and in the tufo beneath, on the side of the rock, are carved the faces, the curlu foot, the diadem, and the sceptre. M. D'Hancleville believes this to have been the tomb of Tarquin the Elder; because he received these regalia from the Etruscan flates, and because the tomb stands on the estate which belonged to him. There are other basso-relieves cut in the tufo, representing the combats of lions and gladiators, with other apparently domestic subjects, on the sides of a tomb at Corinto, the ancient Tarquinium: and although these works may be considered as Etruscan, yet there are reasons for thinking they are of Grecian origin; for Pliny (lib. 55. c. 12.) says, "that Demaratus, the father of Tarquin the Elder, in Hetruria, who was afterwards king of Rome, flying from Corinth, was accompanied by the modellers (scultores) Eucira and Engrammus, by whom modelling was brought into Italy." There are, indeed, works known to be Etruscan, in the gallery of Florence; among which are several square cimeral urns of terra cotta: some of them bear basso-relievos of Grecian subjects, and these are much the best; the rest are of an execution and manufactures equally ordinary. A terra cotta frieze of small figures, seven different subjects, was found some years since at Velletri, and preferred in the Borgian Museum. This seemed to be of the oldf Etruscan style: but illi, as antiquarians have believed the figures to be Grecian, and the frieze itself to be copied from a Grecian original. So far this likewise must be considered as a production of the Grecian school. There is a print from one of these subjects, representing two women in a car drawn by two winged horses; the first head-piece, vol. iii. of Winkelmann's History of the Arts of Design, Fea's edition.

The taste for carved or chased plate of gold and silver was introduced at Rome, by the immense quantity which Lucius Scipio brought in triumph from the spoils of Aisa, consisting of 1,400 pounds weight of chased silver, and 100,000 pounds of gold valus, about 150 years before Christ. Pliny describes the finickyness of the Romans afterwards in works of this kind. "The value of silver varies, by the wonderful inconstancy of the human disposition, not approving long the production of any workshop: now we seek the Etrurian, now the Cidian, now the Gratin, now basso-relievo sharply cut; and now pictures expressed in lines."

Modelling in Luca, called poflicien by Pliny, was practiced under the full emperors, with extraordinary beauty, freedom, and flight of execution; and may be seen in the ornaments of the bath of purification at the temple of Isis at Pompeia, and the baths of Livia in the palace of the Caesar at Rome.

It may be proper to enumerate some of the finest detached basso-relieves in the Roman collections, previous to those existing in the ancient buildings. In the Villa Borghese is one of young women in fine drapery, holding each other by the hand, and dancing. The figures are almost round; it is distinguished by beauty and simplicity. The sleeping Endymion of the Capitol; the sentiment of which is perfect, the figure elegant, and the execution bold: the Perseus delivering Andromeda from the rock; likewise in the Capitol: the large fragment of Antinous, in the Villa A. bani: to which may be added, a most beautiful frieze on one side of the cortile of the palace Santa Croce, of Neptune and Amphitrite, sea-nymphs, tritons, and marine animals; and another beautiful frieze in the palace Della Valie, of victors laicening bulls to Mithras. Some others will be noticed under particular heads.

The alto-relievo of Augus and Telephus, mentioned with so much rapture by Winkelmann and some of his followers (see the Monumenti inediti, plate 72.), will only be noticed here to expose an hypercriticism. It is highly extolled for having three plans of objects in proportionate gradations of relief: it is self-evident that objects placed one beyond the other on a ground, must have different gradations of projection; but as this work has nothing else to recommend it particularly, either in character, sentiment, or composition, what has been said is sufficient to shew, that an indifferent work may become the object of admiration, by the magic of technical jargon, where sentiment, expression, a beautiful design, composition, harmony of parts, and all those particulars which can alone constitute excellence, are wanting.

Of the basso-relievos executed whilist the arts full retained some perfection under the Roman emperors, no specimens are remaining of those compositions of figures which adorned the pediments of buildings. A fragment of the frieze on the Temple of Minerva in Rome, near the Capitol, is still in tolerable condition; there are several prints of it in the "Admiranda Romanorum." There are likewise in the different collections, detached specimens and fragments of friezes, panels, and dies of pedestals. But the greatest number of basso-relievos in their original places, is on the triumphal arches and columns; and the greatest profusion of subjects is to be found on the sarcopliagi. We shall pass the more readily over these, because we have already noticed whatever is most excellent in this department of sculpture, in the ruins of Athens. The following triumphal arches are enriched with basso-relievo: those of Augustus, at Sibza and Rimini; that of Trajan, at Beneventum; and at Rome, those of Titus, Marcus Aurelius (the basso-relievos of which are preserved in the Capitol, although the arch is detached) that of Severus; the gold's arch; and that of Constantine. The noblest composition, perhaps, among them is the apotheosis of Faustina, from the arch of Aurelius. (See Bartoli's Triumphal Arches.) The arch of Constantine is remarkable
able for its sculpture, part of which was done in the reign of Trajan, and the rest under Constantine; some of the former as remarkable for its grandeur, beauty, and boldness, as the latter for its barbarity; shewing the miserable decay of the arts in the course of 240 years. The two battles, the figures in which are as large as life, forming friezes under the cornices of the imposts in the middle opening of the arch, are grand and animated compositions, in a noble style of sculpture (see plate 42. and the following, in the Veteres Arcus Augustarium). Two obelisks on the arch of Severus will show, that sculpture had declined considerably from the best ages. The principal baso-relieves occupy very large figures, containing figures, animals, cities, forts, and great warlike machines, on different plans, irregularly distributed, with regard to perspective; and thus, when viewed at such a distance that the detail becomes indistinct, they present the appearance of rude work irregularly rough, and disagreeable as mixed with regular and magnificent architecture: unlike the friezes in the temples of Athens, which, as they have only one plan of figures, each simply and beautifully conceived, when viewed at a distance in which the detail disappears, they present to the eye a composition of lines distinct and harmonious, forming an ornament. It is also to be observed, that the small figures in these great figures are bold boldly relieved, that they interweave with and destroy the effect of the smaller architectural members near them.

The triumphal columns demand our particular attention, not only for their magnificent design, structure, and materials, but also for the immensity of baso-relieve which covers them. But here we may observe, that imperial grandeur, by the endeavour to outstrip, falls short of real greatness; and that where too much is expected or intended, too little is the result. With respect to the very conception of the Trajan column, a doubt has been entertained, whether a tower might not have allowed of a more grand and simple design for the purpose of a stupendous structure, than a Tuscian column mounted on a Corinthian pedestal. But notwithstanding the doubts of some judicious and unprejudiced persons on this point, the column has been the wonder and delight of all beholders for 1600 years. The spiral baso-relieve, reaching from the bottom to the top of the shaft, represents Trajan's first and second expedition against the Dacians, and his victory over their king Decebalus. Viol (in his Itinerary of Rome) says, "they count upon it upwards of 2,500 figures, without reckoning horses, elephants, arms, machines of war, and an infinity of other objects," to which may be added the four eagles on the corners of the pedestal, bearing fasces of laurel, and the arms on the side of the pedestal, all of matter, and the last mentioned of the most delicate and laborious execution. But here a defect must be noted, in justification of the first observation on this noble monument, that although the figures increase somewhat, both in size and projection, as they approach the top of the column, yet it is certainly true, that any person standing on the ground cannot see the objects distinctly above one-third of the height of the shaft, beyond which all is confusion. Does it not follow, that if figures of that size were intended to be seen, they should not have been raised above one-third of the column; and if they were intended to be seen at a greater distance, their size should have been proportionally increased? That this is an optical defect cannot be denied; yet critics have taken pains to make their readers believe, that every thing relating to perspective in this column was beyond the reach of most modern comprehension for excellence; when any person acquainted only with the very first principles of perspective, must perceive no attention whatever has been given to linear perspective from the top to the bottom of the column: such injudicious praiseful praise only the absurdity and ignorance of the eulogists. Certainly the ancient sculpture contains whatever is truly excellent and admirable in the art; but let us choose the objects which are really polished of these qualities; always distinguishing between beauty and the want of it; and then we cannot bellow our praises too liberally, nor study with too much diligence those perfections we would imitate, or be thoroughly acquainted with. The Antonine column is covered with baso-relieve, representing the victories of Marcus Aurelius over the Marcomanni. The sculpture is inferior to that on the Trajan column; and figures, having more projection, deform the outline of the shaft at a near view. The Theodobian column at Constantinople, drawn by Gentil Bellini (see Monfacon), induce us to believe that sculpture did not decline so hastily in the East as in Italy.

Marble sarcophagi do not seem to have been used in Rome much before the time of Caius, whose wife Cecilia Metella was buried in one. The fronts and ends of these collins, from that time for many ages afterwards, were decorated with figures. Some of the finest compositions of the ancients are to be found upon them, most probably copied from Greek originals, by Roman manufacturers at first; or copied from the Ancients, and occupied an extent of two miles in his work, as has been supposed from the quantity of sculpture finished and unfinished found on the foot, as well as an inscription which confirms the fact. The sublimity of the subjects leads us to think, that some have derived their origin from Poictes, Polycletus, and other of the greatest masters; as it is fearedly possible such groups and such expression as we see in these bad copies, could at first have been produced by inferior artists. Among them are the stories of Prometheus, Medea, Phaeton, Orestes, Ajax, the anger of Achilles, Bacchus and Ariadne, the fall of the giants, the judgment of Paris, &c. &c. These continued to be repeated till after the time of Constantine, when subjects from the Old and New Testament succeeded, but these were so barbarous that they merit no farther notice at present; and indeed the removal of the first of empire to Constantinople had so depopulated Rome of riches and ability, that little effort could be expected in the West, and the little that was left became the successful prey to the Northern invaders, and the unavoidable distraction of time, for the following six centuries. Bas-reliefs of the eighth century, round the capitals of columns, representing Charlemagne and other figures, are in the Museum of French Monuments at Paris. There is also a bas-relief of Samson killing the lion, on a capital in the crypt of St. Peter's church, Oxford, done in the time of Alfred. Like all the works of thefe ages, they are barbarous and unmeaning. In 1605 the Pisans began to build their cathedral, the old bronze gate of which contains a series of subjects from scripture in bas-relief; but so rude and grost, that they must be considered as the very beginnings of art. There is a baso-relieve of the acts of Abraham forming capitals to a group of columns, in the well door of the cathedral of Carrara, carved between 1100 and 1200, which is rather more detailed, though the figures are gross and disproportioned, not being above five heads high. Similar speculations may be seen of this age in different countries of Europe. From the first feeble efforts to revive sculpture. In such attempts as have been just mentioned, little improvement was made till towards the year 1550, when Nicolo Pisano having diligently studied some antique baso-relieves on sarcophagi at Pisa, was employed in carving similar ornaments of sacred subjects, in several
several cathedrals building at that time in different parts of Italy. He was assisted by his son John, and among other pupils, by two who seem to have been particularly favored, Annipoli and Lapo. Besides being architect to several cathedrals in Italy, Nicolo, with the aid of his pupils, carved some baso-relievo in marble; which were works of wonderful merit in that age, and would certainly deserve considerable admiration and respect in any other time or country, for beauty, sentiment, truth, and beauty of execution. The following descriptive notice is a Story from the Life of one of our savours; on the pulpit and baptistery of Pisa; similar figures on the pulpit of the Duomo of Siena and Pistoia. But the greatest and most admirable of these works is on the front of the cathedral of Orvieto. This front is one of the most splendid, both for materials and art, that the mind can conceive, or the resources of nature furnish. It is built of Statuary marble, wrought with the nicest care, and ornamented with the most delicate labour; the builder mouldings and smaller pillars are relieved by Mosaic tiles of the most splendid colors and gold; and magnificent Mosaic paintings of sacred subjects finish the decoration immediately under the cornice. The battlements between the great and two side doors, from the height of six feet to that of twenty feet, is covered with subjects from the Bible in a great number of divisions representing all the principal facts, and concluding with the Resurrection, Judgment, and final definition of the good and wicked; the subjects are divided by rows of columns, of uncommon delicacy and fancy. There is also a relief by Nicolo, on the church of St. Martin at Lucca, of the Defeat of the Crofs, which is extremely pathetic and simple. The baso-relievo on the oldest bronze gate of the baptistery of Florence, by Andrea Ugolino of Pisa, after designs by Giotto, of the Life of St. John the Baptist, are simple and grand. Donatello, born in Florence 1483, executed bronze baso-relievo on the two pulpit of St. Lorenzo in that city; the principal subjects are the Crucifixion and Interment of our Saviour, in which the expression is admirable. Vellano of Padua, his fellow, made some fine baso-relievo of bronze in the church of St. Anthony in that city. But the work of this description which obtained the highest reputation in that age, was the second bronze gate, executed by Lorenzo Ghiberti, his father, and other assistants, for the before-mentioned baptistery of St. John in Florence. On it, ten compartments are filled with subjects from the Old Testament, beginning with the Creation and ending with the meeting of Solomon and the Queen of Siciba; the spaces between the panels are adorned with foliage, heads, and beautiful figures of prophets and fylpis; the architrave is ornamented with treloons of flowers and birds; of so perfect an execution that they seem to be cast from nature: the whole is of gilt bronze. Vafari relates that Michael Angelo said, "It desired to be the gate of Paradise." Certainly an admirable fancy, delicacy, exprefion, grace, and execution, are to be found in every part of it; but its general character is rendered trivial by the introduction of so many plans, so much landscape and architecture in perspective, with the affectation of picturesque effect in the chiaro-foreo. But this fault might be palliated by the remembrance, that perspective was a new discovery to the moderns, wonderfully admired at the time: it had turned the brains of Paolo Uccello, a painter of great merit; and it is not to be wondered at, if Lorenzo Ghiberti, who had practiced painting, should have fallen into the delusive hope of adding a new charm to sculpture, which in fact belongs to painting exclusively.—From this time little can be said in commendation of the practice of baso-relievo. Memory was substituted for imitation, fancy for nature; and the consequence was, that various species of affectation which are called manners. The schools of John of Bologna, Algardi, Remini, wear out this remark; and whoever takes the trouble to examine their productions in this department of sculpture will see, that art more than nature has been their object. Within the last century a number of circumstances have combined to develop the principles of sculpture, and a considerable emulation has been excited to attain its real perfections. A prodigious number of ancient statues, groups, busts, and baso-relievo in marble and bronze, as well as pictures, have been discovered; there have been magnificently and judiciously arranged, not only in the public museums of Italy, but in private collections of the different countries of Europe. Such admirable works have excited universal curiosity and interest, the number of books on the subject have increased by learned men and elegant critics: students have repaired in greater numbers than formerly from all parts to copy those works with great diligence; the number of competitors has produced emulation, each one endeavoring to distinguish himself above his competitors; thus they have laid up a large stock of ability for employment in their own countries, where taste for the arts of design has been gradually increasing; so that now there are sculptors in Italy, France, England, Germany, &c. who have produced baso-relievo of great merit, as well as other works of sculpture.

Williamson has said, "that Sculpture, like an elder sister, has introduced and led her younger sister, Painting, into the world. This is elegantly said, and on that account is likely to obtain currency more than for the certainty of its truth. What additional value does one art acquire over the other by being older? Both arts are noble and virtuous pursuits, the fine productions of both afford intellectual and rational delight; and there is difficulty enough in the way to excellence in both, to execute the utmost stretch of the most powerful genius who have engaged, or may engage, in the study of them. It should seem from Pinty's account, lib. 35, c. 3. and c. 12. that the beginning of painting and baso-relievo were alike; for the first advances towards it were made by Dibutades taking the inspiration of an outline. Aricles the Corinthian, and Telephanes the Syracusan, made the first efforts towards painting before colour was used, by outline alone. But take this quittance of a moment, let us go to those considerations which are of real importance to the subject, and to the subject of baso-relievo. It has already been shown, that baso-relievo, from the earliest ages, was used as representative writing; and the right and only good purposes to which writing as well as speaking can be applied is to honour God, and to recommend and distinguish whatever is virtuous in public or private, and useful among men. Thus was baso-relievo employed in the bold ages by the ancients, according to their several systems of theology, philosophy, and ethics: and thus only it should be employed; for when it is applied to other purposes, it is a deviation from the original intention, ceases to be useful, and must engage the art in the representation of persons and things below that standard at which he should constantly aim. Phidias gave a perfection to his Jupiter which all admired all men, and induced them to believe he had been favoured with a revelation of the god, by the human representation of power, majesty, beauty, and wisdom. And we shall find that whatever appears admirable, perfect, or lovely, in the representations of the ancient deities or heroes, is some mental or bodily perfection. The Christian religion presents performances and subjects no less favourable to painting and sculpture than the ancient classics: angels and archangels should be as perfect in youth and beauty as the youthful divinities of Greece. The heroes of the Old Testament bear so striking a resemblance to those of Greece, that eminent moderns have mistaken them.
then for the same persons. Nothing can be found in the fages of Greece, more august or sublime than in the patriarchs or prophets: they were equally inhabitants of warm climates, favourable to the display of the human figure; and their clothing and arms were nearly similar. Indeed it may be falsely alleged, that the b& relievo of the Laid Judgment by Nicolo Pianati, the Crucifixion and Entombing of our Lord by Donatello, and some of the panels in Ghiberti's gate, prove that the Bible presents subjed, and those almost innumerable, of greater interest, and as abundant in all the excellence of composition, as any to be found in the classical authors: such subjed are the proper decorations for churches and other public edifices of most importance to society, which should be perpetual schools of instruction. After the choice of subjed, the economy and manner of treating are next to be considered. And here several hints may be found in Aristotle's poetics, and in the conduct of the Greek tragedies, as useful for the composition of a bas-relievo as a poem; with this difference, a poem embraces a succession of times, but a bas-relievo one moment only: and where this rule has been trespassed, the same perfon has been introduced twice over. That one moment must represent an action, and so many figures should be admitted than are necessary: because the increase of number is the distraction and loss of expresion. The sentiment, the expression, and every part should be as elevated and advantageous as the nature of the subjed will admit.—Concerning the execution, the bas-relievo of the Parthenon temple of Theseus, the others in the mines of Athens, and a few more which are truly Greek, must be set up as the perfection of what has hitherto been done: the compositions are intelligible, because the figures are distinctly seen on the back-ground and not crowded one behind another; the drawing of the figures is from chosen examples, feelingly, forcibly, and faithfully copied; the pathos of the subjed is not weakened by the introduction of building in perspective, or the affectation of chiaro-fouro, which attempts to introduce the dimness of painting in bas-relievo. Agatharchus employed perspective in painting scenes, but Pheidias and Polycleus knew that the form and expression of the human figure was the object of their sculpture.

Some very fine and extraordinary antique bas-relievo enrich the collections of England:

The tomb-stone of Xanthippus, and a man curving a borse, both about the time of Pheidias, are in the collection of Charles Townley, esq.

The marquis of Lansdown has a Greek bas-relief of Chalcas, as large as life.

At Wilton House there is a fine example of the death of Meleager, and a small but curious Hercules and B&gle, a bas-relievo composed of Mosaic, in natural colours, which is supposed to be the only one of the kind.

The celebrated B&firiini, in the possession of the duke of Portland, is of dark blue glass, bearing figures in bas-relievo of white enamel or glass of admirable workmanship. (See Belfort Sepolcuri Articha, Plate 84.) Fragments of bas-relievo in similar materials have been found in the ruins of the Caesars' palace in Rome, where they had been fixed in the wall.

John Hawkins, esq. the Grecian traveller, possesses a beautiful small bronze bas-relievo of Paris, Helen, and two Gennii, which he brought with him from Greece.

Plate I. 1. Contains an Egyptian hieroglyphical pithnry. 2. An Hindoo b&-relief. 3. A Persian bas-relief. 4. Jupiter with the thunder and trident, a Greek gem of the oldst style.

Plate II. 1. Minerva fubduing Hercules, from a very ancient Greek patara of bronze in the British museum. 2. Apollo and Hercules contending for the tripod.

Plate III. The tomb-stone of Xanthippus, father of Pudicvs.

Plate IV. 1. A capital of a column in the west door of the cathedral of Carrara, representing part of the history of Abraham; a work of the twelfth century. 2. A beautiful Greek bas-relievo, near the tino of Pudicvs, of Zeltona, comforting their mother Ariope, from the Villa Albani.

BASSOMPCRiER, Francis De, Bas-relief, in Biography, was a defendant of a distinguished family in Lorraine, and born in 1579. Engaging himself in military service, he rose to the office of colonel-general of the Swiss, and in 1622, to that of marshal of France. He was also employed in a diplomatic capacity to Spain, England, and Switzerland. In these employments he was distinguished by his talents and conduct, and particularly by his sagacity, politeness, and generosity. He secured all the European languages, was an adept in gastronomy, and much addicted to play. By his bons mots, which were sharp and droll, he offended cardinal Richelieu; who caused him to be confined in the Bastile in 1651, where he continued for twelve years till the death of this minister. In this retreat he passed his time in reading and writing; and the historical works which he composed were the productions of his imprisonment. These are "Memoirs, containing the history of his life, and of the most remarkable occurrences at the court of France from 1739 to 1761," 3 vols. 12mo.; "An account of his Embassies," 2-vols. 12mo.; and "Remarks on the History of Louis XV. by Duplessis," 12mo. These works abound with curious particulars and interludes of satire. After his liberation he was reduced to his rank of colonel of the Swiss, and was fixed upon as governor to the young king Louis XVI., but excused himself if on account of his age and infirmities. Towards the close of his life he became very corpulent, and died of an apoplexy in 1746. Gen. Biog.

BASSOON, in Mefic, from bas-pan, Fr. low sound, in opposition to hautbois, to which it is the natural bafe. Like the hautbois, it is played with a reed, and is a continuation of the scale downwards. It is composed of four different pieces or tubes, which when separated are bound together like a fugotte, but the Italians call it a fugotto. It has three keys of communication to open and shut the ventages, which from the length of the instrument are out of the reach of the fingers. It has a crook, or mouth-piece, to which the reed is fixed. (See RESD.) The whole length of the instrument is eight feet; but reduced to four, by being doubled up like a trumpet, is convenient in performance and carriage. Its compass is three octaves, from double AA in the bafe to A in the second space of the treble; of which the tones and semitones are as complete as on an organ, or any other keyed instrument. Every performer is not able to produce a lower sound than double BBB in the bafe, or a higher than G in the second space in the treble.

In the latt age, Milker was the favourite performer on the bafion in England at all public places; but we have at present Mr. Holmes, a superior performer, at least in point of tone, to any that we have ever heard elsewhere. A scale for this instrument will be found in the musical plates.

The two Bazzozzi of Turin rendered these kindred instruments, the hautbois and bafion, famous in Italy, during the middle of the last century. See BAZZOLI.
BASSORA, BASSORA, or BASSA, in Geography, a famous city of Asia, in the Arabian Sea, situated on the western banks of the Shat al Arab, which is a navigable canal, formed by the junction of the Euphrates and Tigris. This canal is navigable for vessels of fifty tons to the Euphrates, and thence to the gulf of Persia, from which it is distant about 15 leagues north-west. This city was founded in the year 656 by order of Omar, the second caliph, to hinder the commerce that subsisted between the Indians and Persians, and to secure the command of the two rivers by which goods imported from India were conveyed into all parts of Asia. The first colony was composed of 800 families, but the situation was so wisely chosen that it soon became a flourishing and populous capital, and a place of trade, frequently inferior to Alexandria. The air, though excellently hot, is pure and healthy; the meadows are covered with palm-trees and cattle; and one of the adjacent valleys has been celebrated among the four paradises of gardens of Asia. Under the first caliphs, the jurisdiction of this Arabian colony extended over the southern provinces of Persia. The city has been fortified by the tombs of the companions and martyrs; and the wells of Europe still frequent the port of Bassora as a convenient station and passage for the Indian trade. Merchants of Arabia, Turkey, Armenia, Greece, Jews, and Indians reside here; the English and Dutch have their consuls, and their ships come from India laden with various kinds of merchandise. Thence from Bengal, which arrive from the month of March to June, bring white ivory, silk, muslin, ballad, fision, fan- dal, and other woody things, vauntich, rice, lead, European tin and iron. From the coast of Coromandel they bring thicker cloths, white or blue; which are sold by the Abians for their garments. From the coast of Malabar they bring cardamom seeds, pepper, &c. From Surat they receive all kinds of gold and silver fillets, turbanis, blue cloths, indigo, and silk; of which the Persians are the chief purchasers for the manufacture of their fabrics. The principal merchandise of the Dutch are spices and coffee from Java. Some Abians bring flax, and others bring pearls from Bahrein, and coral from Mocha. The neighbouring countries also furnish merchandise for exchange; of which the most valuable are the ancient copper of Persia in small cakes, drugs of various kinds, grain when it is allowed to be exported, and dried fruits. The merchandise is sold for ready money, and passes through the hands of the Greeks, Jews, and Armenians. The Banians are employed in changing the coin current at Bassora for that which is of higher value in India. The abbe Raynal values the merchandise annually brought to India at 32,000,000; of which the English furnish 17,000,000. The Dutch 85,000, and the Moors, Banians, Armenians, and Arabs furnish the remainder.

Bassora has been subject to the Turks ever since the year 1668; and, like other cities, tributary to that dominion, is governed by a cadi appointed by the prince of Bassora. But it may now be regarded as belonging to an independent Arabian prince, who pays dubious homage to the Ottoman Porte. The prince allows full liberty to all nations to come and trade to his capital; and the police of the city is so well maintained, that a person may pass freely through the streets at any time of the night. The prince derives his chief revenue from the exchange of money for the horsera and camels that are sold here, and also from his plantation of palm-trees, which is said to be 96 miles in length. The horsera that are bred in its vicinity are in great repute, and are sold at a high price. The income of the prince from the several articles of money, horsera, camels, and dates, is so great, that he has a considerable surplus after discharging all the expenses of his tribute and government. The opulence of Bassora is owing partly to the extensive commerce which is carried on by the intervention of this town between Asia and Europe, partly to its being a place whence letters may be dispatched into all parts of Europe, particularly England and Holland, by way of Damascen and Aleppo, for which purpose Arabs, who are very swift-footed, are employed; and partly to the resort of Perian caravans in their pilgrimages to Mecca, where they pay considerable duties to the government, and exchange many valuable commodities. The number of inhabitants is computed to be about 52,000; the majority being Arabs: Persians are principally Turks and Armenians. The latter are the merchants, and some of them are very respectable. As to the religion of Bassora, besides Mohametans, there are Syrian Jacobites and Niflians, and monks from Europe; and afo some modern Scandalians, whom they call disciples of St. John. The town is of great extent, and surrounded by a wall of clay, said to be twelve miles in circumference. The Bazar, or marketplace, is about two miles long and well supplied. The buildings of this city are mostly constructed after the Turfih manner. The whole country about it is so low, that it is prevented from being inundated by a dyke or bank extending between three and four miles along the coast, and built of large square stones so well cemented together that the sea cannot effect it, though the sea runs strongly against it at the extremity of the Persian gulf. Bassora is 210 miles S.W. of Ispanig, and 100 S.E. of Aleppo. N. lat. 34° 24'. E. long. 42° 39'.

BASSOS, or BASSOS, Cape, lies in the Indian sea, on the eais coast of Asia in Africa, in N. lat. 45° 12'. E. long. 47° 37'.

Bassos de Banyas, shohals in the Indian ocean, lying off the eais coast of Zonguebar in Africa, in S. lat. 5° E. long. 48° 5'.

Bassos de Chaga, or shohals of Chaga, are situated in the Indian ocean, in S. lat. 6° 43'. E. long. 68° 20'.

Bassos de India, shohals of India, are situated N. E. cally from the cape of Good Hope, and are called in some charts Jews Rocks, between Madagascar island on the east and the coast of Africa on the west, about Sofala. S. lat. 23° 30'. E. long. 40° 41'.

BASSUES, a town of France, in the department of the Oers, and chief place of a canton in the district of Mirande, 5 leagues W.S.W. of Auch.

Species. B. jaceata. Abl. Guin. 217. 105. Stems herbaceous, three or four feet high, branched; leaves alternate, ovate, acute, smooth, entire, on a petiole about an inch long; the largest 10 inches long and 4½ broad; flowers in axillar corymb, green, and very full. A native of Guiana. In wet woods, flowering and fruiting in June. Martin's Miller's Dist.

BASSUEL, in Geography, a town of France, in the department of the Morin, and chief place of a canton in the district of Vitry la France, 6 miles N.N.E. of Vitry.
BASSUEL, Peter, in Biography, born in Paris in 1706, was early initiated in the knowledge of surgery, by attending the hospitals and the lectures of the principal teachers there. In 1728 he was admitted to practice; and the academy of surgery being instituted the following year, he was nominated by the king one of the first members. In 1744, he was chosen demonstrator royal in therapeutics. He took part in the dispute on a question then much agitated, Whether the heart was shortened in its fyllole, or contraction, to expel the blood from the ventricles? But his opinion was formed, Haller says, from theory only. His dissertation on the subject was published in one of the medical journals of the time. He died June 4th 1757. Haller. Bib. Chr. Elw. Dict. H.8.

BASSUL, in History. See BASUL.

BASUM, in Geography, a town of Germany, in the circle of Weitbahn, in the county of Hoya, with a noble abbey; 16 miles west of Hoya.

BASSURE, Sand, begins at Amblètreuf, a little to the south of St. John's, on the coasts of France, close to the shore, and stretches out S.W. by S. and S.W. by B.

BASTA ISLAND, is situated on the coast of Norway, 5 leagues N.W. by W. from the Sizers' island, which lies 4 leagues at W. by N. from Acker found.

BASTA, Giros. Cant. in Biography, an Epirote by descent, was born at La Rocca, a village near Tarcentum; and devoting himself to the military professions, he was commander of an Epirote or Albanian regiment of horse, when the prince of Parma assumed the government of the Low Countries in 1577. Under this great general he perfected himself in the military art, and was preferred by him to the post of commissary-general of cavalry, and also employed in many important enterprises. The principal theatre on which his talents were exhibited, was the war in Transylvania and Hungary, where, in 1601, he gained a signal victory over Siegmund Battori, and took the town of Claufenburg. Having completed the ruin of Battori, he granted him peace on condition of his renouncing all rights over Transylvania. However, the severities exercised by Balta against the protestants of that country did great injury to the cause of the emperor, and the Imperialists, under the count Belgioj, were defeated. Although Balta, in 1605, could not prevent the Turks from taking Strigium or Gran, he made a judicious arrangement before Comorra, which hindered their further advances. Having made a peace, he soon after died in 1607. Balta was the author or two professional works that are much esteemed; the “Maestro di campo generale” (Quarter-master general), printed at Venice, in 1665; and the “Gioven della cavalleria liggiosa” (Discipline of the Light Horse), Frankl. 1612. Gen. Dict.

BASTA, in Ancient Geography, a town of Italy, in Luporia, on the east coast, at a small distance N.E. of the Salentine promontory.

BASTA, in Geography, a town of Egypt, 42 miles N.E. of Cairo, and 51 S.E. of Manfara.

BASTA, or Bokiar, a place of trade on the coast of Africa, before which is a road with 20 to 25 fathoms of water, and tolerably good ground.

BASTA, in Natural History, a species of Spongia, found in the Indian sea, and called by Rumphius bokia maris, Bokla laut. It is somewhat rigid, blackish, with undulated divisions; itc round. Pallas. Found adhering to stones, and is about the thickness of a finger. Gmelin, &c.

BASTAHRAGH, in Antiquity, a city or company at Rome, who carried the ficial species out of the provinces to Rome or Constantinople. The directors of these were called poepitati kthagaram. The word is derived from kthaga, which properly imports the office of carriage or conveyance; from kthaga, portare, to carry. The denomination ballagarii has also been given to those who carry the images of saints at processions. Du-Cange.

BASTAL, in Geography, the name of a romantic and fertile vale of Switzerland, lying in the direct road from Bielle to Soleure, through the midst of the Jura mountains.

BASTAN, a town of Albian Turkey, in the province of Natafia, 30 miles S.W. of Amatia.

BASTARD, Thomas, in Biography, a clergyman and poet of the sixteenth century, was born at Blansfird in Dorsetshire, and educated at Winchester school; whence he was removed to New College, Oxford, and chose perpetual fellow in 1585: but indulging too much his talent for literature, he was expelled the college for a libel. He afterwards became chaplain to Thomas earl of Sutfield, lord-treasurer of England, and, by his interest, vicar of Bere-Regis, and rector of Hamer in his native county. He was a person of great natural endowments, and skilled in the learned languages, a celebrated poet, and, in his later years, an excellent preacher. Towards the close of his life, he was deranged and involved in debt; and being confined in prison at Dorchester, he died in an obscure and mean condition in 1618. He was thrice married: first, as inform us in one of his epigrams, in his youth for love; again, in materer age, for money; and a third time, in his old age, for a nurse. His poetical performances, which were admirably versed, were “Epigrams,” and a Latin poem, entitled, “Magnae Britanniae,” London 1605.

BASTARD, in Law, a natural child, or one that is not only begotten, but born, out of lawful wedlock.

The word is of Saxon etymology, and is compounded of bagan, vile or ignoble, and flæt, or flært, original.

According to the civil and canon laws, a child doth not remain bastard, if the parents afterwards marry; but it is an indispensable condition of legitimacy, according to our law, that it shall be born after lawful wedlock. In this respect our law is far inferior to the Roman; because marriage being principally defined for ascertaining some person to whom the protection, maintenance, and education of the children should belong, this end is better answered by legitimating all children born after wedlock than by legitimating all issue of the same parents, even born before wedlock, so as wedlock afterwards enforces a proof of which, Blackstone alleges the following arguments. 1. Because great uncertainty will generally attend the evidence, that the issue was really begotten by the same man; whereas, by confining it to the birth, and not to the begetting, our law has rendered it perfectly certain, what child is legitimate, and who is to take care of the child. 2. Because the Roman law, by which a child may be continued a bastard, or made legitimate, at the option of the father and mother, by a marriage “ex partibus,” opens a door to many frauds and partialities which our law prevents. 3. Because by these laws a man may remain a bastard till forty years of age, and then become legitimate by the subsequent marriage of his parents; and thus the main end of marriage, or the protection of infants, is totally frustrated. 4. Because this rule of the Roman law admits of no limitations as to the time or number of bastards so to be legitimated; but a dozen of them may, 20 years after their birth, by the subsequent marriage of their parents, be admitted to all the privileges of legitimate children. This is plainly a great discouragement to the matrimonial state; to which one principal inducement is usually not only the desire of having children, but also the desire of procuring lawful heirs. Whereas our constitution guard against this indecency, and at the same time afford sufficient allowance to the frailties of human
human nature. For if a child be begotten while the parents are single, and they will endeavour to make an early separation for the offence by marrying within a few months after, our law is so indulgent as not to bar-furit the child, if it be born, though not begotten by lawful wedlock, in lawful wedlock. But there is an incident that can happen but once, since all future children will be begotten, as well as born, within the rules of honour and of civil society. Upon reasons like these, Blackstone supposes the peers to have acted at the parliament of Merton, when they refused to make that children born before marriage should be deemed legitimate. Stat. 20 Hen. III. c. 9. See the introduction to the great charter, ed. Oxon. 1759, sub anno 1253.

Hence it appears, that all children born before marriage are bastards by our law. But if a man marries a woman grossly big with child by another, and within three days after, she is delivered, the child is no bastard. 1 Dan. Abrig'd. 729. If a child is born within a day after marriage between parties of full age, if there be no apparent impossibility that the husband should be the father of it, the child is no bastard, but supposed to be the child of the husband. 1 Roll. Abr. 358. Moreover, all children born so long after the death of the husband, that by the usual course of gestation they could not be begotten by him, are bastards. But this being a matter of some uncertainty, the law is not exact as to a few days. It appears, upon the whole, that what is commonly considered as the usual period is 40 weeks or 280 days; but if the child be born some time after, it only affords presumption, not proof of illegitimacy. This uncertainty of the period of gestation has given occasion to a proceeding at common law where a widow is suspected to feign herself with child, in order to produce a supposed issue to the estate; an attempt which the rigour of the Grecian confittutions esteemed equivalent to the most atrocious theft, and therefore punished with death. In this case, with us, the husband presumptive may have a writ "de ventre inspicendo," to examine whether she be with child or not; and if she be, to keep her under proper restraint till delivered; which is entirely conformable to the practice of the civil law: but if the widow be, upon due examination, found not pregnant, the presumptive heir shall be admitted to the inheritance, though liable to lose it again on the birth of a child within forty weeks from the death of her husband. But if a man dies, and his widow soon after marries again, and a child is born within such a time as that by the course of nature it might have been the child of either husband; in this case, he is laid to be more than ordinary legitimate; for he may, when he arrives to years of discretion, choose which of the fathers he pleases. (Co. Litt. 8.) To prevent this among other inconveniences, the civil law ordained that no widow should marry "infra annum lustum," a rule which obtained to early as the reign of Augustus, if not of Romulus: and the same constitution was probably transmitted to our early ancestors from the Romans, during their stay in this island; for we find it established under the Saxon and Danish governments. L. L. Ethelr. A. D. 1008. L. L. Canut. c. 71.

As bastards may be born before the coverture or marriage, beget, or after it is determined, so also children born during wedlock may in some circumstances be bastards. As if the husband be out of the kingdom of England, or as, the law somewhael-loosely phrases it, "extra quatuor maria," for above nine months, so that no access to his wife can be presumed, her issue during that period shall be bastards. (Co. Litt. 244.) But generally, during the coverture access of the husband shall be presumed, unless the contrary be shown; (Sulk. 123. 3 P. Wms. 276. Stra. 295;) which is such a negative as can only be proved by the king himself to be elsewhere: for the general rule is, "presumptio pro legi-

1. Tim. iv. 24. 2 Pet. 2. 1. 3. 1 Pet. i. 37. 2. 1. 5. 3. 1. 5. 4. 1. 5. 5. 1. 5. 6. 1. 5. 7. 1. 5. 8. 1. 5.
BASTARD.

Bastards might be legitimized by subsequent marriage, or by the emperor’s letters. The emperor Anastasius allowed fathers to legitimize their bastards by adoption alone; but this was abolished by Julian and Julianus, lest by this indulgence they should authorize concubinage. The pope has sometimes legitimized bastards. Nay, the holy see has on some occasions dispensed not only with illegitimates, but with the offspring of adultery, as to spiritual considerations, in allowing of their promotion to episcopacy.

Accordingly the civil law differs from ours in this point, and allows a bastard to succeed to an inheritance, if after its birth, the mother was married to the father (Nov. 89, c. 8); and also, if the father has no lawful wife or child, then, even if the concubine was never married to the father, the heir and her bastard son were admitted each to one twelfth of the inheritance (Ibid. c. 12); and a bastard was likewise capable of succeeding to the whole of the mother’s estate, although she was never married; the mother being sufficiently certain, though the father is not. But our law, in favour of marriage, is much less indulgent to bastards.

An attempt was once made to introduce the civil law here in this respect, by declaring children legitimated by a subsequent marriage; but it was rejected; and it was upon this occasion that the barons of England assembled in the parliament of Merton, A. D. 1572, made that famous answer, "Nonnumquam Anglie natura." 1 Hen. III. c. 9.

But though bastards are not looked upon as children to any civil purposes, yet the ties of nature hold as to maintenance, and many other intentions; as, particularly, that a man shall not marry his bastard son or daughter. L. Raun. 63. Comb. 536.

A bastard was, in strictness of law, incapable of holy orders; but though that were dispensed with, yet he was utterly disqualified from holding any dignity in the church. Fortesc. c. 40. 5 Rep. 58. But this doctrine seems now obsolete; and there is a very ancient decision, that a felon should have benefit of clergy, though he were a bastard. Bro. Clergy 20. In all other respects, there is no distinction between a bastard and another man: whereas the civil law, which has been exulted for its equitable decisions, made bastards in some cases incapable even of a gift from their parents, Cod. 6. 57. 5. A bastard may even be made legitimate, and capable of inheriting, by the transcendent power of an act of parliament, and not otherwise (4 Inst. 36); as was done in the case of John of Grant’s bastard children, by a statute of Richard II.

Bastard, with regard to the several modes of its trial, is distinguished into general and special bastardy. Tih the statute of Merton already recited, the question whether born before or after marriage, was examined before the ecclesiastical judge, and his judgment was certified to the king or his judges, and the king’s court either received or rejected it at pleasure. But after the solemn protest of the barons at Merton against the introduction of the civil and canon law in this respect, special bastardy has been always tried at common law; and general bastardy has alone been left to the judgment of the ecclesiastical judges, who in this case agrees with the temporal. (2 Inst. 29. Rewis’s H. A. Eng. Law. 85. 201.) General bastardy, tried by the bishop, compels two things. 1. It should not be a bastardy made legitimate by a subsequent marriage. 2. That it should be a point collateral to the original cause of action. If the ordinary certify or try bastardy without a writ from the king’s temporal courts, it is void; and the certificate must be under the seal of the ordinary. 1 Rol. Abr. 301, 352.

Special bastardy is two-fold: 1st, Where the bastard is the gift of the action, and the material part of the issue; 2dly, Where those are bastards by the common law that a e “mulieres” by the spiritual law. (Co. Litt. 134. 1 New Abr. 314. 1 Rol.)
BASTARD Scarlet is a name given to r.d dyed with whole madder, as coming nearest to the bow-dye, or new scarlet. Bastards are also an appellation given to a kind of faction or troop of banditti, who rove in Guiana about the beginning of the fourteenth century, and joining with some English parties, ravaged the country, and set fire to the city of Xantin. 

But I may suppose them to have consisted of the natural sons of the nobility of Guiana, who being excluded the right of inheriting from their fathers, put themselves at the head of robbers and plunderers, to maintain themselves.

**BASTARDY** is a defect of birth objected to one born out of wedlock.

Enfuita there remains, against the course of antiquity, that bastards among the Greeks were in equal favour with legitimate children as low as the Trojan war: others, however, have shown that there never was a time when bastardy was not in disgrace. (See Homer. II 6, v. 261. S. pl. ocel. Ajas, v. 1370. Emp. Ion. v. 589.) In the time of William the conqueror, bastardy seems not to have implied any disgrace; for that monarch does not scruple to assume the appellation of bastard. His epistle to Alan, count of Brecy, begins, " Ego Wilhelmus, cognomen bastardus." 

BASTARDS, Arms of, in Heraldry, should be crossed with a bar, fillet, or traverse, from the left to the right. Bastards were not formerly allowed to carry the arms of their father, and therefore they invented arms for themselves: and this is full borne by the natural use of a king.

BASTARDY, Right of, Droit de Bastardise, in the French Law, is a right, in virtue of which the effects of bastards dying intestate devolve to the king or the lord.

BASTARDY, Trial of, See BASTARD.

BAPTISTAE, in ancient Geography, a people who as first inhabited that part of European Sarmatia that corresponded to a part of Poland and Praufia, towards the Vistula, and who afterwards approached the more southern parts, and established themselves to the left and right of the Tyas or Danneker. The era of their war with the Goths, and of their conquest of these territories, is not precisely ascertained. M. Frerer refers it to the interval between the years 282 and 285. B.C. Tacitus says, they had houset; and hence it has been inferred that they were not Sarmatians, because they dwelt in huts. Livy considers them as Gauls, and Strabo presumes that they were a nation of Germans. They feem, however, to have inhabited the region that lay north of the Carpathian mountains, and to have gradually extended themselves towards Poland and the Borylthen. Many learned persons have represented them as a colony left by the Gauls on the other side of the Carpathian mountains, when they made their proffes, under the conduct of Brennus, from the east towards the west. M. de Peytton says, that they may be regarded as the founders of the Rumanians and Selonians.

BASTATA, in Geography, a small island on the easter coasts of the island of Sumatra. S. lat. 1°. E. long. 103° 30'.

BASTAVOE, a bay on the easter side of Yell, one of the Shetland islands.

BASTELICA, a town of the island of Corfica, 5 leagues E.N.E. of Ajaccio.

BASTERIA, in Bastia, See CALYCASTHA.

BASTERNA, in Antiquity, a kind of vehicle or chariot used by ancient Roman ladies.

Pappas thinks, that basterna was first written for *vasterna.* Rosweild says, it should be *via flerna,* which he concludes from Iphidore, who says, *Laflerna,* *via flerna.* But the word seems better derived from the Greek *φαρα,' ports, to carry.*

Salamis
Salmamus observes, that the bastlerna succeeded the 
letras, or litter; from which it differed very little, except that the 
litter was borne by the shoulders of slaves, and the bastlerna 
borne by donkeys. Cafaunfo says it was borne by 
males. F. Daniell, Mobilion, &c. affirms it was drawn by 
oxen, to go the more gently; and Gregory de Tours gives 
an instance of its being drawn by wild bulls. The mode 
they called the coves, or cage: it had soft cushions or beds, 
besides glases on each side like our chariots. The mode of 
building bastlerna passed from Italy into Gaul, and thence into other 
countries: and to this we owe our chariots, which, though 
we call them currus, yet have they no conformity to the 
ancient currus, but are in effect bastlerna improved. The 
bastlerna appears also to have been used in war, for the car-
rying of baggage.

BASTI, now Bazza, in Ancient Geography, a town of 
Spain, in Betics, north-east of Acri, and near the moun-
tains which separate Beticia from Tarraconensium.

BASTIA, in Geography, a sea port town of Albazia, in 
Turkey in Europe, over against the island of Corsi, at the 
mouth of the river Caffoni. N. lat. 39° 40'. E. long. 
20° 35'.

BASTIA, a city and sea port of Corsi, the capital of the 
island, or of the department of Golo, is situated on its north-
west side, and commanded by a lofty mountain, in the centre 
of which the sea forms a small bay, defended by a mole. It 
is divided into two parts, called "Terra Nuova" and "Terra Vecchia," in the former of which is a citadel, surrounded 
with fortifications. Its harbour, though good, is not large, 
and affords convenient anchorage for vessels of a small size, 
but is unfit for the reception of ships of war: and its com-
erce is insignificant. In 1799, Corsica revolted from 
Genoa: and in 1794, it was attacked by lord Hood, and 
captured by the British fleet and army. The number of in-
habitants in its cantons is supposed to be about 10,000. N. 
lat. 42° 35'. E. long. 6° 30'.

BASTIA Minore (Rumifius), in Natural History, a kind of 
sponge, supposed to be the Specia, or ventubra, of Gemin.

BASTIDE, in Topography, an appellation given in the 
southern departments of France, to small country-houses, 
built by individuals of easy circumstances, in the vicinity of 
the towns.

Bastide de Montfort, La, in Geography, a town of France, 
in the department of the Tar, and chief place of a canton in 
the district of Gaillar, 5 miles N. E. of Gaillar.

Bastide de Saron, La, a town of France, in the department 
of the Arro, and chief place of a canton in the district of 
Poix: 24 leagues N. W. of Tarascon. The place contains 
1764 and the canton 5712 inhabitants: the territory 
includes 13724 kilometres and 12 communes.

Bastide, La, a town of France, in the department of the 
Lot, and chief place of a canton in the district of Goudon. 
The place contains 1161 and the canton 5914 inhabitants: 
the territory includes 2124 kilometres and 11 communes.

Bastide de Jourdan, La, a town of France, in the depart-
ment of the moons of the Rhone, and chief place of a 
canton in the district of Apt, 4 leagues S. E. of Apt.

Bastide d'Armagnac, La, a town of France, in the de-
partment of the Gers, and chief place of a canton in the 
district of Nogaro, 44 leagues N. N. W. of Nogaro.

Bastide Clerc, La, a town of France, in the depart-
ment of the Lower Pyrenees, and chief place of a canton in 
the district of Basone. The place contains 2000 and 
the canton 6934 inhabitants: the territory includes 1500 kilome-
tres and 7 communes; 4 leagues W. of Orthez.

BASTILE denotes a small antique castle, fortified with 
turrets.

Such was the battle of Paris, which seems to have 
been the only castle that retained the name: it was begun to 
be built in 1360, by order of Charles V. and finished in 1583, 
under the reign of his successor. Its chief use was for the 
custody of state prisons.

Of the plan and structure of this edifice, which was for 
several ages appropriated to the edifice purposes of un-
feeling despotism, and which might be justly considered as 
the abode of human misery, and of the regulations by which 
it was governed, it is now needless to record any particular: 
for it was assailed and totally destroyed at an early period of 
the revolution in France, viz. on the 14th of July, in the 
year 1793. Those who are curious in acquainting them-
se1ves with its history, will find their curiosity gratified in 
a volume entitled "The History of the Bastile, &c." pub-
lished in 1790, 8vo. The most satisfactory information re-
ting to the prisoner in the iron mask, who was confined in 
this wretched dungeon for many years, and concerning 
whom many conjectures have been made, is communicated 
to the public in a work entitled "Memoirs of the Marechal 
8vo. The secret is said to have been extorted from the 
regent by his daughter, who delivered it to the duke de 
Richelieu. From the account given in this work it appears, 
that this unfortunate prince was the twin-brother of Louis 
XIV. born eight hours after this monarch, and who was 
the unhappy victim of superstition and cruelty. His father, 
Louis XIII., being weak enough to give credit to a pre-
cident of some impostor, that if the queen should be deli-
ered of twins, the kingdom would be involved in civil war, 
ordered the birth of this prince to be kept a profound se-
cret; and had him privately educated in the country as the 
illegitimate son of a robanian: but on the accesion of 
Louis XIV. the young man gave indications of having dis-
covered his parentage, of which his brother being informed, 
order him to be imprisoned for life, and to wear a mask, 
in order to prevent his being recognized.

BASTIMENTOS, in Geography, small islands near the 
shores of Darian, at the mouth of the bay of Nombre de 
Dios. They form a good harbour; and one of them has an 
 excellent spring. N. lat. 6° 30'. W. long. 79° 45'.

BASTINADO. See Bastonado.

BASTION, in the Modern Fortifications, a large mass of 
earth usually faced with stones, sometimes with brick, rarely 
with stone, standing out from a rampart, whereof it is a 
principal part; and answering to what in the ancient fortifi-
cation was called proxisorium, or a bulwark.

Bastions, some false, were first introduced by Zicco the 
Bohemian; others attribute the invention of them to Achmet 
Bahlou, in the year 1480, mentioning the fortification of 
Otranto as the first instance in which they were used. How-
ever, they were well known soon after the year 1500; for 
Tartalea gives a plan of Turin, which had been completely 
fortified for some time with four bastions, in his Quaesiti 
Inventioni diversae, published in 1546. The first bastions, 
such as those of Turin, and of Antwerp, which was fortified 
about the year 1540, were small, and removed at a great 
distance from each other: but they were made much larger, 
and brought nearer to each other in the citadel of Antwerp, 
crested under the direction of the duke d'Alva, about the 
year 1566.

A bastion consists of two faces and two flanks, and an 
opening towards the centre of the place called the gorge. 
The faces are the lines BC and CS (Plate 1. Fortification, 
fig. 1.) including the angle of the bastion. See Face. 
The flanks are the lines BA, SD. The union of the two 
faces makes the obtuse or falant angle, called also the an-
gle of the bastion, BCS.

The union of the two faces to the two flanks makes the 
five-angles called the shoulders, or epaules of the bastion. 

And
And the union of the two other sets of the flanks to the two curtains, the angle of the flanks of the balion.

The foundation of the balion, &c. of a work consisting of flanks and faces, is that part only in fortification, viz. that every part of a work must be seen and defended from some other part; mere angles, therefore, are not sufficient, but flanks and faces are indispensably requisite. Thus, if the balion consisted of four flanks, &c. as A. B. C. D. &c., all the points may be defended from the flanks; these being none, viz. in the face B. C, but what may be defended from the opposite flank E. F., nor any in the curtin A. B., but may be defended from the adjacent flanks B. A, and E. F. nor in any one flank B. A, but may be defended from the other E. F.

For the proportions of the faces, they are not to be less than 50 toises, nor more than 60; or differing little from 100 yards.

The flanks of balions are better as they are longer, provided they stand at the same angle under the line of defence; hence the flank must stand at right angles to the line of defence. Indeed, in the ancient fortification, the flank was made at right angles to the curtin, so as to have the angle out of the enemy's eye; but this is now provided for, by withdrawing the lower part of the flank two or three paces farther towards the capital line; which part, thus withdrawn, is better, if made concave, than rectilinear; and if double, with a ditch between, than if flanke.

The business of disposing the flanks of balions makes the principal part of the art of fortification; it is that on which the defence principally depends, and which has introduced the various forms and modes of fortifying.

If the angle of the balion be less than sixty degrees, it will be too small to give room for guns; and beside, so acute as to be easily broken down by the enemies' guns; to which may be added, that it will either render the line of defence too long, or the flanks too short: it must therefore be more than sixty degrees; but whether or not it should be a right angle, some intermediate angle between sixty and ninety, or even whether or not it should exceed a right angle, is still disputed; though those are generally preferred, which are not much less than 90°, and not exceeding 120° or 130°. Hence it follows, that a triangle can never be formed, because either one or all of the angles will be either sixty degrees, or less than sixty.

Balions are of divers kinds, solid, void, flat, cut &c.

Balions, solid, are those that are filled up entirely, and have the earth equal to the height of the rampart, without any void space towards the centre.

Balions, void, or hollow, are those surrounded with a rampart and parapet, only ranging round their flanks and faces, so as to leave a void space towards the centre; where the ground is so low, that if the rampart be taken, no re-trenchment can be made in the centre, but what will lie under the fire of the besieged.

Balions, flat, is a balion built on a right line in the middle of the curtip, when it is too long to be defended by the balion at its extremes.

Balions, cut, is that whose point is cut off, and in lieu thereof has a receding angle, or an angle inward with two points outward: this is sometimes also called balion cut with a tenaille; and is used either when, without such a contrivance, the angle would be too acute, or when water, or some other impediment, hinders the carrying on of the balion to its full extent.

Balions, composed, is when the two sides of the interior polygon are very unequal, which makes the gorges also unequal.

Balions, regular, is that which has its due proportion.

Vol. III.
The bastinado is a punishment used among the ancient Greeks, Romans, and Jews, and still obtains among the Turks. The Romans called it *flagellation*, *fistula admodo*, or *fistula exit*, which differed from the *flagellation*, as the former was done with a stick, the latter with a rod or scourge. The *flagellation* was a lighter punishment, and inflicted on freemen; the *flagellation* a severer, and referred for slaves. It was also called *typanum*, because the patient here was beaten with sticks, like a drum.

The penalty is much in use in the East to this day. The method thereto practised is thus: the criminal being laid on his belly, his feet are raised, and tied to a stake, held fast by officers for the purpose; in which posture he is beaten by a cudgel on the soles of his feet, back, chin, &c. to the number of one or more hundred blows. Calmet. Dict. Bib. tom. i. p. 263.

For the method of inflicting this punishment at Algiers, see ALGIERS. Dr. Shaw (Trav. p. 252.) suggests that it was in this manner, that St. Paul was "three beaten with rods." 2 Cor. xi. 25. The Chouiers, whose office it is to inflict this punishment at Algiers, appear to be no other than so many Roman lietors armed with their fasces. The frightful ad ad the Chinsce punishments is the *batihilation*, which is only used for chastising those who have been guilty of very trivial faults. The criminality of the offender determines the number of blows which he must receive; but the lowest number is twenty. The punishment in this case is considered merely as a simple paternal correction, without any infamy attached to it; and it is ordered by the captain to be inflicted on his cottiers, who are afterwards received into favour and treated with respect. The *bat*, or "pau-tée," used for this punishment, is a piece of bamboo, a little flatted, broad at the bottom, and polished at the upper extremity for the convenience of being more easily handled. Every mandarin may use it at pleasure in certain cases, either when any one forgets to salute him, or when he admitters public justice. On such occasions he fits gravely behind a table, upon which is placed a bag filled with small sticks, while a number of petty officers stand around him, each furnished with some of these "pau-tées," and waiting only for his signal to make use of them. The mandarin takes from the bag one of the little sticks which it contains, and throws it into the hall of audience. The culprit is then seized, and stretched out with his belly towards the ground; his breeches are pulled down to his heels, and an athletic domicel applies five smart blows of his "pau-tée," another succeeds, and belows five more, if the mandarin draws another small baton from the bag, and thus, by gradation, until the judge is pleased to make no more signals. The criminal, who has undergone this chastisement, will then throw himself upon his knees before the judge, incline his body three times to the earth, and thank him for the care which he takes of his education.

Croft's China, vol. ii. p. 52. &c.

BASTONIER, or Batonier, in the French Law, an ancient advocate, erected yearly according to seniority, to be the head or master of the community of advocates and attorneys. He is president of the board held for maintenance of the order, and discipline of the fallos. To him also belongs the commision of the inferior judges, when put under interdict, so long as the interdict lasts.

Bastonier is also used for him who keeps the staff of a community, and carries or follows it in processions.

BASTOVA, in Geography, a town of European Turkey, in Albania, 18 miles south of Durazzo.

BASTWICK, John, in Biography, M. D. born at

Writtle in Essex, in 1593, after passing through the usual school education, was sent to Emmanuel college in Cambridge, where, however, he did not continue a sufficient time to take his degree; but with the view of qualifying himself for the practice of physic, he quitted England to visit the principal universities on the continent, where, at that time, the different branches of medicine were better taught than in his own country. At Padua he was admitted to the degree of doctor in medicine; but engaging early in theological disputes, and thence exciting the resentment of the clergy, he soon found himself involved in troubles, from which, at a late period, he speedily escaped with his life. In 1624, and before he returned to England, he published at Leyden, " Elnechus Religionis Papillicis, in quo probatur, neque Apostolicam, neque Catholicam, in quo Romanam silet," 1624; and soon after his return, "Flagellum Pontificis et Episcoporum Latinorum." Though he declared, in the preface to this work, that nothing in it was intended to affect such bishops as acknowledged their authority from kings and emperors, yet our English prelates, either suspecting that some things in his book were levelled at them, or perhaps not enduring that the conduct of ecclesiastics should be exposed with such freedom by a lay writer, and fearing if he was suffered to go on the same weapon might be turned against them, he was cited by them before the high-cummission court, fined 1000l. and sentenced to be excommunicated, to be debarred the practice of physic, to have his books burnt, and to remain in prison until he made a reparation. After being confined two years in the Gatehouse, he published " Apologia ad Praetores Anglicos;" but that procuring no remission of his sentence, it was soon followed by "The New Litany," in which he taxed the bishops with having an inclination to popery, and exclaimed against the severity and injustice of the high-cummission's proceedings against him. For publishing this work, he was sentenced, by the same court, to pay a fine of 5000l., to stand in the pillory in Palace-yard Westminster, and there lose his cars, and to suffer perpetual imprisonment in a remote part of the kingdom. The same sentence was, about the same time, in 1637, passed and executed upon Prynne and Burton. Balfwick was conveyed to Launceston castle in Cornwall, and thence removed to St. Mary's castle in the isle of Scilly, where no one was permitted to visit him. The house of commons, however, in 1640, ordered him, as well as the others, to be brought to London, whither they were attended by vast multitudes of people, with loud acclamations of joy. The proceedings against them were voted illegal, and they were ordered to be remunerated out of the revenue and effects of the archbishop of Canterbury, and the other lords of the commision who had condemned them. Balfwick was alive in 1648. The time of his death is not known.

G-a Dic. D-i.

BASVILLE, in Geography, a sea-port town in the island of Martinico.

BASZEU, a river of European Turkey, which runs into the Pruth, near St. Plirovoz, in Moldavia.

BAT, in Zoology. See VESPERTILIO.

BAT, in Commerce, a small base silver coin, current in divers parts of Germany and Switzerland, at different prices.

The bat or flademouse at Nuremberg, is equal to four croizters; at Zurich, to ½ of the French crown; at Basel, Schilhauen, &c. to ½; and at Berne and Friburg to ½ of the crown. These last are called short bats.

BATA, in Botany. See MUSA.

BATA, in Geography. See BATTA.

BATAANO, a town on the fourth side of the island of Cuba in the West Indies, seated near a large bay, opposite Pinas.
BAT

Pinus isca, and about 50 miles south-west from the Han- 
vannah.

BATABLE LAND. See Bataable.

BATAICOLO, or Batacoalo Bay, in Geography, lies on the 
coast of the island of Ceylon, in N. lat. 7° 57', E. long. 8° 3'. It extends to the south between the main 
island and a narrow track of land on the east side of it, and is well sheltered from molf winds. The Port town, fo-called, is on the west side of this bay, or gulf, 5; leagues N. E. of 
Colombo. The bay is about 30 leagues to the S.S.W. of 
Trincomalee. Batacoalo is a place of comparatively few 
importance; but the surrounding country, and the bold gro-
tefque rocks which skirt its shores, have deservedly attracted 
particular attention.

BATAICARANG POINT, lies on the coast of the 
island of Sumatra.

BATALHA, a monastery in Portugal, near Lisbon, 
about 62 miles to the north of Lisbon, founded by John 1, 
at the close of the fourteenth century, in accordance of 
the great victory over the king of Calde, and reckoned one 
of the most noble monuments of what is called the Gothic 
style of architecture. It has been particularly described by 
Mr. James Murphy.

BATAI, a town of Asia Minor, in the provence of 
Natal, and south of Kastoria.

BATAIARDIERE, a place in a garden, prepared for the 
painting of fruit trees, which being transplanted thither 
from the nursery, are to be placed in espaliers, or elsewhere, 
to supply the place of dead trees.

BATAAS, in Botany. See Convolvulus.

Bataas. See Potato.

Bataas, in Entomology, a species of Acarus, found on the 
potatoes in Surinam and some other parts of South 
America. It is rather rough and fangueous; anterior legs as 
long as the body. Fabulous.

BATAVI, in Ancient Geography, are supposed to have 
been originally the same people with the Catti or Cattans, 
who dwelt beyond the Rhine; and being driven from their 
country by a domestic insurrection, they settled at the ex-
treme borders of Gaul, in an island called "Island Bata-
vorum," formed by the mouths of the Rhine and the ocean. 
According to this description, the Batavians policed South 
Holland, part of the country of Utrecht, and the island of 
Batav in the dukedom of Guelderland. The early history 
of the Batavi is involved in considerabe obscurity. It is 
certain, however, that about 54 years before the Christian 
aera they were distinguished by their valour, and attracted 
the attention of Caesar, who formed an alliance with them.
He encouraged them to serve in the Roman army; and they 
appeared to have fought with him against Pompey at 
Pharsalas, and to have assisted Augustus in the battle of 
Aegium. They assisted Caesar in his attacks upon the 
Gauls, and they everywhere meet and dispersed that fer-
ocious and warlike people. The Batavian cavalry bore the 
highest reputation, and the infantry fought with the same 
order, discipline, and intrepidity in the marshes and waters 
as upon the firm land; and even the Romans dreaded their 
resentment. They became the body-guard of the emperors, 
who repaid equal confidence in their fidelity and courage; 
and they retained this honourable trust till they were dis-
missed by Galba, though with tokens of favour and clemence. 
In all important expeditions, in every dangerous enterprise, 
and where obstinate obstacles was required, the Batavians 
were selected. They generally composed the forlorn hope of 
the Roman army, furnished the first shock of the enemy, and 
made the first attack with an impetuosity peculiar to them-
selves. They were not only honoured by the title of allies 
to the empire, but distinguished by the appellation of the 
friends and brothers of the Romans; which denomination 
was particularly applicable to the inhabitants of Betaw, an 
Island formed by the Rhine and Vistul or Wash. Their 
government seems to have been monarchical, and it is un-
fettered that Claudius Civilis was descended from their 
kings. But, though the Romans indulged them in an ex-
tension from tributes and taxes, it was not consistent with 
the views they had adopted of universal dominion to allow 
them the enjoyment of their liberty. They built towns, 
and made establishments in their territories; and this rude 
people, flattered by the luxury and the amusements which 
they introduced among them, did not immediately perceive 
the dangers which directed them. They were 
formed, however, informed of the treachery of their allies, by 
the oppression and injustice which they began to exercise. 
When Vitellius and Otho disputed the empire, and the 
German nations attempted to recover their liberty, the 
Batavians followed their example. Alarmed for the interest 
and the rights of their nation, Julius Paulus and Clavius 
Civilis set themselves to oppose the practices of the Romans, 
and to emancipate themselves from their dominion. But 
when Otho was put to death at Caesar, the Roman commander, considering them 
as rebels, made himself master of their persons; and having 
brought the former, he loaded the latter with chains, and 
sent him to Rome. The death of Nero, however, which 
happened about this time, delivered Civilis from the danger 
which threatened him; and the weak and impotent Galba 
suffered him to return to his country, without inquiring into 
his crime, or into his merit. This illustrious chief then 
prepared to gratify his resentment, and to recover and 
vindicating the liberty and honour of his nation. He called an 
assembly of his community, and representing the evils of 
tyranny, incited a dissolution of submission and servitude. 
His countrymen submitted themselves without reference to his 
council; and writing with the Friuli and the Cornutes, he 
declared war against the Romans. Gaining an accession of 
strength from the Tongrians, who deserted the Romans, 
and from some natives of Batavia, who served as rowers in the 
Roman fleet, he was enabled to defeat the Romans and put them to 
flight. He was afterwards joined by eight Batavian cohorts, 
who abandoned Vitellius, by whose orders they were march-
ing to Rome, and also by some other German tribes; and thus 
aided and encouraged, he obtained some further suc-
cess. But upon the arrival of Cerialis, the Roman general, 
he received a total overthrow, and was at length obliged to 
abandon his own island, whether he had retreated, to retire 
beyond the Rhine, and to submit to the Romans. A con-
ference taking place between Cerialis and Civilis, the ilinc 
of it was an entire submission on one side, and an unfavoured 
pardon on the other. The Batavians remained in the same 
condition in which they were before the war broke out; 
that is, exempt from all tributes, and only obliged to supply 
the Romans with troops when required. We know little 
more of the ancient history of the Batavians than that the fierce 
and warlike spirit of the people obliged the Romans 
to maintain strong garrisons on the banks of the Rhine; 
that they revolted against Constantine; that they performed 
signal services to Thoedius in Britain; and that, with the 
rest of the empire, they fell under the power of the Franks; 
and were governed by Charlemagne, and his descendants, 
until, upon the decline of that house, the great lords and 
oficers of the crown, taking advantage of the weakness of 
the reigning princes, rendered their governments hereditary 
in their families. From the Batavi, the seven united pro-
vinces derived the name of Batavia, which since the French 
revolution has been recognized in the appellation of the 
Batavian

BATA
Batavia, a citadel of Vindelicia, so called from the coasts Batavia, in Geography, the celebrated capital of the Dutch polt-summer in the East Indies, and demonstrated the beauty of its situation, but the beauty of its building, and its immense trade, is a sea-port town on the north coast of the island of Java, situated very near the sea, on a fertile plain, bearing evident marks of having been left or thrown up by the sea, in the kingdom of Jaccata, upon the river of that name, which, running through the middle of the town, divides it into two parts. To the north of the city is the fea-shore; behind it to the south, the land rises with a gentle, and scarcely perceptible, acclivity towards the mountains, which lie 15 or 16 Dutch miles, or leagues, inland; one of which, as being very high, bears the name of the Blue mountain. This city was founded in 1619 by the governor-general, John Peterzen Koen, who captured and destroyed the town of Jaccata, near the spot where the former town was situated; and he gave it the name of Batavia, though it is said he wished to have called it "New Horn," from the place of his nativity, "Horn," in North Holland. Although it was then an insignificant place, with regard both to strength and beauty, he declared it the capital of the Dutch settlements in India; and his choice of the situation was judicious, and his plan well carried out; that it rose with unparalleled rapidity to that degree of magnificence and importance which it has reached, must be attributed to the admiration and terror of all the more eastern nations of India. It still retains a very considerable rank and influence; although, for the last 50 years, it has much declined both as to opulence and population. The form of the city is an oblong square, 3 miles long, and 4 miles broad, intersected by the river already mentioned, which runs from north to south, and is crossed by three bridges. The breadth of the river, within the city, is about 300 or 310 feet; and passing the castle and admiralty wharf, it bifurcates itself into the sea. On both sides of its mouth are long piers of wood and brickwork, about 3,600 feet long, taken from the mouth of the city; between which, on the west side, the vessels belonging to the city are laid up and repaired; but along the east side, the passage is open for the lighter ships, which go into and out of the city with the cargoes of the ships. Opposite to the outer point of the eastern pier is a thoroughfare, commonly called the "Water-fort," constructed of a kind of coral rock and having, mounted or dismounted, fourteen guns, and two howitzers. It consists of a parapet, retained by a wall; but the parapet has been much neglected, and the wall is nearly destroyed by the constant working of the sea. This fort is protected on the land side by a moat, and to the sea, on the north-west, by extensive flats, over which even boats cannot pass. The only good approach is that by the channel, which it is and defends. On the west shore, about a quarter of a mile from the water fort, is a battery, mounting seven guns, bringing down the river; and opposite to this is a battery of six guns, facing the river, and two to the eastward. Each division of the city on either side of the river has two canals, running parallel with the longest sides, and intersected at right angles by cross-canales. These canals join the great canal, or river, at the distance of half a mile from the entrance; and below their junction is laid a boom of wood, armed with iron spikes. The city is encompassed by a wall of coral rock, serving as a facing to the rampart behind it; and also by a moat, having several sluices, into which water is conveyed from the river. Sir George Staunton says, that a part of the town wall is built of lava, which is of a dark blue colour, and of a very hard dense texture, emitting a metallic sound, and very much resembling some of the lava of Vulcano. It is brought from the mountains in the centre of Java, where a crater is still smoking. The rampart is defended by twenty or twenty-one battlements, which, as well as the wall, are in a various state. Small projections, of various forms, are constructed at intervals of about 500 feet, each of which generally mounted three guns. At short distances from the town, three or four small flag-stands on earth are erected in particular places, probably for defence against the inhabitants of the island. The castle or citadel of Batavia, which was formerly on the sea side, is now, by the continual increase of the mud banks before it, distant from the sea more than 100 rods, and is seated on the east bank of the river. It covers about 200 rods of ground, and is a regular square fortres, built or coral rock brought from some of the adjacent islands, composed of that material. It has neither ravines nor outworks. Two guns are mounted on each flank, and two, or sometimes three, on each face, neither "en barbette," nor "en embrasure," but in a situation between both, having the disadvantages of both, without the advantages of either. The wall is of masonry, about 24 feet high. It has no ditch, but a canal encompasses it at some distance. It has no cordon; and the height of the exterior side of the work is about 500 feet. Between the moat and the buildings within the fort, on the south side, is a large area or esplanade. In the centre of the buildings that look towards the city, is a great gate, and then a broad passage, with warehouses on each side, leading to another esplanade, on the north side, enclosed between the ramparts and the buildings, which are appropriated to the use of the company. The government house, which forms the left wing of the buildings looking to the south, is provided with numerous and convenient apartments, but uninhabited. In it is a large hall, in which the council of India generally assemble twice a week. Near this is a little church or chapel, called the castle church; and at a small distance is a corps-de-garde, where a party of dragoons always maintains guard. Over the castle bridge is a spacious plain or square, planted with tropical trees, which afford an agreeable shade; and the entrance into it from the city is over a bridge and through a large fluted gate, mounted with a lofty cupola, from which rises an octagonal turret with a large clock, the only public one at Batavia. On the left side of the gate is a large building, serving as a corps-de-garde, having in front a long gallery, relining upon a row of piliers; where is usually posted a captain's guard of grenadiers. On the west side of the square stand the company's artillery-house, and the diocesan or provision magazine, both of which extend to the side of the river, so that the goods are taken in and out of the lighters with the greatest ease. On the opposite side is the iron-magazine, and the grafs-plate or place of execution, which is an artificial square eminence, upon which are several piers and some poles; and behind it is a small building, with windows, opening towards the place of execution, where the crucifical of justice may behold the completion of their sentences. Upon the plain are arranged pieces of iron and brass artillery, and other warlike implements.

Batavia has five gates; and near to this on the north side, to the west of the river, is the admiralty wharf; and near this, the warehouses for naval stores, and the workshops of the carpenters, coopers, sail makers, and smiths, with other offices and houses that relate to the shipping. In the south-east corner of the city, close to the ramparts, lies the workmen's quarters.
quarter, called "Ambigtse varter," in which all the workmen and laborers employed by the company relieved. Besides a great number of Europeans, there are more than a thousand natives who belong to this quarter.

Besides the public buildins already mentioned, Batavia has a town hall, which is well situate: two large and convenient hospitals, and several churches; three of which, within the city, are appropriated to the returned religion, in which service is performed in the Dutch, Portuguese, and Malay languages: and one without the gates, called the outer Portuguese church. There is also a Lutheran church not far from the castle, provided with a tower, and a very handsome pulpit. These churches are supplied every Sunday by twelve clergymen of the reformed religion, and three Lutheran ministers. One of these clergymen is deputed, once every year, or sometimes only once in two years, upon a visitation to the company's possessions on the west coast of Sumatra; and to the individuals thus employed, the visitation is rendered more desirable by the merchandise which they take with them for sale. The Chinese have also several temples, which are tolerated by government; but the exception of the Roman Catholic religion is obliterated by prohibited.

In the districts round Batavia, immediately subject to the Dutch, it is calculated, says Sir George Staunton, that near 30,000 Javanese families are fished, containing upon an average 5 per cent. of the population in the whole; the city of Batavia, including the suburbs, contains nearly 8,000 houses. Valentyn (cited in the Mod. Un. Hist.) states the number of houses in the city and suburbs at 4,770. Havens, a more recent Dutch writer, who was long resident at Batavia, and who published his account in 1778, estimates the number of houses in Batavia at 3,700; but he does not say whether he included the suburbs. The number and description of inhabitants in 1778, according to this writer, were as follows: viz. 468 European barbers, 5,572 native Christians, 4,573 Malays, or men without flannel of all nations, 23,099 Chinese, 289 Amboynese, 278 Bandamese, 950 Moors, 254 Gentoo, 1,852 Malays, 324 Doutaminers, 1,963 Macalleers, 5,707 Boogineers, 104 Tumoreers, 189 Men-hoarets, 85 Sambuarems, 13,673 Balis, 33,428 Javanars, and 23,072 slaves; making in all 112,566, exclusively of wives and children, and of the company's servants. The company's establishment consisted, in 1776-1777, of 610 persons in civil, and 55 in ecclesiastical employments, 69 gunners and sailors, 125 belonging to the artillery, 875 seamen and mariners, 1,571 soldiers, and 923 mechanics; in all, 4,221 Europeans, besides 707 natives in their service.

The houses at Batavia, belonging to the Dutch, are well built, chiefly of brick, clean and spacious, and their construction is, for the most part, well adapted to the climate. The doors and windows are wide and lofty; the ground-flours are covered with flags of marble, which being sprinkled frequently with water, gives a pleasant coolness to the apartment, but when Sir George Staunton visited the place, he could not help expressing his regret at the prospect of the houses being untended, a circumstance which indicated a declining settlement. The houses of the Chinese are low, and crammed with people. Most of them dwell in the Lautneren and western suburbs, which are called the Chinese "Campus." Before the revolt of the year 1748, they had the half quarter of the city allotted them, to the west of the great river; but when in that connection all their houses were burnt to the ground, the whole quarter was converted into a "pallis," or market, where at present all kinds of provisions are daily exposed to sale. Before the perpetuation of this massacre, several thou-

and Chinese adventurers returned to Batavia, allured by the prosperity of their countrymen already settled there. The number of these colonists, together with the robberies and murders committed by them, excited a considerable degree of apprehension; which induced Van Imhoff, who was at that time a member of the council, to propose, that those who could not prove that they were gaining an honest livelihood should be seized and transported to Ceylon, and there employed in mining and other labour for the service of the company. The execution of this order produced a tumult and an insurrection; and thousands of the Chinese retired from the city, and collecting a strong force, ravaged the country and assailed the capital. The civil and military inhabitants united in repelling them. But a fire taking place soon after among the Chinese buildings in the city, several of the owners were accused of opposing with arms the extinguishment of it, with a view, as it was said, of allowing the confederacy to spread through the whole town, and in the moment of confusion they might affiliate the Europeans, and become masters of the place. The alarm was such, that the Dutch government gave instant orders to put all the Chinese heads of families to death; and the sailors from the vessels in the road were brought ashore, and induced, for the sake of plunder, to share in executing the bloody edict. All the Chinese, without distinction, men, women, and children, were put to the sword; and the innocent and guilty were indiscriminately exterminated. Whence this barbarous order inflicted has been a subject of unsatisfactory investigation. The governor-general, Valkenier, and his brother in-law Helvetius, were accused by the public voice, of directing the massacre; but their guilt was never proved. The deed itself was condemned by the directors of the company of Holland; and much apprehension being entertained that the fact would excite the indignation of the emperor of China, deputies were sent to him in the following year, to apologize for the massacre on account of the necessity of the case. These deputies were agreeably surprised to find that the emperor calmly answered, that "he was little solicitous for the fate of unworthy subjects, who, in the pursuit of lucre, had quitted the country, and abandoned the tombs of their ancestors." The Chinese, however, are said to have been as numerous as ever in and about Batavia; and it is acknowledged by the Dutch that the settlement could scarcely exist without their industry and ingenuity. The quarter of the suburbs which they occupy is crowded with shops containing all kinds of goods: those of their own manufacture, and such as they receive annually from China, or purchase from the European importations. The number of Chinese, who live both within and without the walls of the city, cannot be precisely determined; but it must be very considerable, as the company receives a poll-tax from them of more than 40,000 rix dollars. Every Chinese who has a profession is obliged to pay a monthly poll-tax of half a ducatoon, or 3s. per annum; but women, children, and those who have no trade, are exempted from this tax. They are under a chief of their own nation, called the Chinacecaptain, who lives within the walls, and has under him ten lieutenants in different districts. A flag is hoisted at his door on the first or second day in every month, and the Chinese that are liable to the tax are then obliged to repair to him for the payment of it. Each house in Batavia pays annually an allument of half a month's rent, which is expended in digging and clearing the canals, and in repairing the town-hall and other buildings belonging to the city. The churches are repaired out of the duties levied upon funerals. At Batavia a bank of circulation has been established for some
some years, which bank is united with the Lombard or bank for lending money on pledges. This bank is under the administration of a director (who is generally a counsellor of India), two commissaries, a cashier, and a book-keeper. Its capital is computed to amount to between two and three millions of rix-dollars, or between 435,000l. and 650,000l. Sterling.

The suburbs of Batavia are remarkable on account of their considerable extent, uncommon pleasantness, and great population. They are inhabited by Indians of various nations, and by some Europeans; but the quarter of the Chinefe is the most populous, and seems of itself a city. None of the streets of Batavia are paved; but along the sides of them near the houses are stone foot-paths, about three or four feet broad. The streets and canals are planted on each side with large trees, generally the "onophyllum cato-phyllon," and "calaba," the "canarium commune," and others of a nearer foot. The Dutch, who are fond of gardens in Holland, have indulged that taste to a great extent at their houses in the environs of Batavia, which are every where intermixed with rivulets, by which the circum- junction rice plantations are inundated and fertilized in the proper season. The country, though it be a fenny district, of which a gentleman upon the spot used the strong expression, "that the air was pestilential, and the water putridous," is nevertheless every where so verdant, gay, and fertile, interspersed with such magnificent houses, gardens, avenues, canals, and drawbridges, and so formed in every respect to please, if health could be preferred in it, that a youth just coming from sea, and enraptured with the beauty of every object he saw around him, but mindful of the danger to which life was exposed, could not help exclaiming, "What an excellent habitation would it be for immortals!" There are five principal roads which lead from the city towards the country, and they are all planted with high and shady trees, and adorned with basidome houses and pleasant gardens.

As to the habits and mode of living of the inhabitants of Batavia, they very much depend on the views and dispositions with which they resort hither, on the situation which they occupy, and on the qualities of the climate. The natives are generally in general too remote from civilization to have any wants that are not easily satisfied, in a warm and fertile climate. No attempt is made to enslave their persons; and they find the government of the Dutch left vexatious than that of others who divide some share of the sovereignty of the island with them. As for the Chinefe, who are constantly resorting hither from China in the vessels called "junks," their views are similar to those which influence the natives of Holland, and they are alike actuated by the desire of accumulating wealth in a foreign land; both the one and the other were trained in their own country to habits of industry; but upon their arrival in Batavia, they are placed in different circumstances, and acquire different manners. The Chinefe, having no prospect of advancement by favour or interest, apply with diligence to the occupation that is allotted them, and by exertion and economy meliorate their condition, without being able to gratify their ambition by the attainment of any public offices. In the city, they become retailers, clerks, and agents; and in the country, they are farmers, and the principal cultivators of the sugar-cane. Thus they at length acquire fortunes, which they value by the time and labour required to earn them; and this gradual acquisition makes no change in their disposition or mode of life; their industry is not diminished, nor is their health impaired. The Dutch, on the contrary, who are sent out by the company to administer their affairs in Asia, become soon sensible that they have the power, wealth, and possessions of the country at their disposal. Those who survive the depredations of the climate, mount by a quick gradation to offices, lucrative but not laborious. Their influence likewise enables them to speculate in trade with great advantage. The drudgery of buiness is readily undertaken by the Chinefe, who, like the native Batavians and Deodasies in Calcutt and Madras, are employed as subordinate instruments; while their principals find it difficult, under such new circumstances, to retain their former habits, or to refit a propensity to indolence and voluptuousness, though often attended with the sacrifice of health, if not of life. Convivial pleasures, among others, are frequently pursued to excess. "The Chinefe," says Stivornius, "are like the Jews in Europe, very cunning in trade, both in the largest dealings, and in the most trifling pedlary. They are so dexterous at money, that a Chinefe will run three times from one end of the city to the other, if he has the prospect of gaining a single penny." He adds; "in doing business with them, the greatest care must be taken to avoid being cheated." In stature they are rather short than tall, and in colour not so brown as the Javans. Their heads are shaved all round, except a bunch of hair on the middle of the crown, which is twisted with a ribbon that hangs down the back. Their dress consists of a long robe of nankeen or thin silk, with wide sleeves, and under it they wear drawers of the same, which cover the legs. In their houses they hang up in certain niches, images of their "jooftjes" or idols, painted on Chinese paper, before which they burn lamps and incence. This jooftje they consider as an evil spirit, and therefore they continually supplicate him not to do them any harm. In their adorations, they prostrate themselves before him, and express their reverence by striking their heads continually against the ground. They likewise consult their idol by a peculiar mode of divination, when they engage in any important undertaking. Notwithstanding this superstition, the Chinefe are accused of gratifying their bulls, by the most detestable violations of the law of nature. Their tombs are magnificent and costly; and great numbers of them are to be seen about half an hour's walk from Batavia, on the road to Jacatra. When a Chinefe of any note dies, his death is formally announced to all the branches of the family. The body is washed, perfumed, and dressed in the best apparel of the deceased. The corpse is then feated in a chair; and his wives, children, and relations, fall down before it and weep. On the third day it is put into a coffin, and placed in one of the bell apartments, hung with white linen, the colour appropriated by them to mourning. In the middle of the apartment is erected an altar, on which is placed the portrait of the deceased, with incense burning near it. On one side of the coffin stand the fons, druzzled in white coarse linen exhibiting every sign of sorrow; while the mother and female relations are heard lamenting behind a curtain. On the day of burial, the whole family assemble, and the corpse is carried to the grave with much solemn pomp. Images of men and women, relations of the family (in the manner of the ancient Romans), and even of animals, together with wax tapers and incensories, are carried to the procession. Then follow the priests with musical instruments; and after them the corpse upon a bier, attended by the fons of the deceased, clothed in white, and leaning upon crutches, as if disabled by grief from supporting themselves. The female relations are carried in chairs, hung with curtains of white silk, that conceal them from view; but their lamentations are distinctly heard; and other women are hired, who are trained to utter shrieks still louder and more piercing. Previously to the funeral, a table with fruits and other estables
A.

They kill round profession wine any of like well and their trusted little dance. arc holding ihape ankles, tea, bright when from a made pieces fuch faces by dinner ladies. are black and jewels feeds, the j, rice of practifed the misfortune, fame addicted, of acquiring artificial courage, an extraordinary dose of opium, and food becoming frantic as well as desperate, they not only lib the objects of their hatred, but sadly doth to attaick in like manner every perfon they meet. till self-preservation renders it necessary to defroy them. They are laid in that flate to be "running a muck;" so called because, during their frenzy, they continually cry out, "amok! amok!" which signifies "kill! kill!" and their fury has been erroneously ascribed to opium, whereas in reality it is the effect of unruly passion. Influences of it are not more common among slaves than among free natives of the country, who in the anguish for losing their money, effects, and sometimes their families, at gaming, to which they are violently addicted, or under the urgency of some other passion or misfortune, have recourse to the fame remedy, with the fame fatal effects. A fondness for play, and also for opium, is not uncommon among the Chinese also at Batavia; but by habits of restraint and moderation they are prevented from falling into the fame frantic exceffes. The Chinese at Batavia are accustomed to keep gaming-houfe, which are the means of seduction and ruin to the greatest part of the slaves in the city; and these pelfs of society are under the protection of the municipal government, the officers of which pay to the company, as a consideration for the profits accruing from them, a monthly contribution.

The mode of living practifed by the Europeans, either from Holland or any other nation, that reside at Batavia, is very nearly the fame. In the morning at five o'clock, or when the day breaks, they rise; and the tables are spread at an early hour. Besides tea, coffee, and chocolate, fish and flesh are ferved for breakfast; and when this is finifhed, Madeira, claret, gin, Dutch small beer, and English porter, are laid out in the portico before the door of the great hall, and pipes and tobacco are prefented to every guest, with a bright brafs jar for a fipping-dish. Trofe who have bufinefs appear at their proper fiations at eight o'clock, and remain employed till between the hours of eleven and twelve. Their dinner hour is one o'clock; but immediately before dinner, two men flaves go round with Madeira wine, of which each takes a large glafs. Then follow three female flaves, one with a fliver jar, containing plain or rofe water for washing; a second with a fliver basin and low cover of the fame metal, piecèd with holes, to receive the water after it has been used; and the third with towels for wiping the hands. During dinner, a band of mufic plays at a little distance. The musicians are all flaves who have been inducted for this purpofe. A confiderable number of female flaves attend at table, which is covered with many dishes. Dinner is immediately fucceeded by coffee. After drinking coffee, each perfon retires to a bed, confiding of a mattrafs, bolster, pillow, and chinett counterpane, but no sheets; and puts on his night-drefs, a muffin cap, and loose long cotton gown. A bachelor is attended by a female flave, who fans him while he ftrets. About fix rife, drefs, ftrep, drink tea, take an airing in their carriages, and form parties for the evening. The morning meetings are compofed generally of men, as the ladies feldom choose to appear till evening. "Married men," says Stavorinus, "feldom give themselves much concern about their wives, nor fhow them much regard. They feldom converse with them, except in ferviceful fubjects, and fuch as concern fociety, with which of course they are little acquainted. Few of these ladies are natives of Europe; but many are defcended from Dutch fettlers here; and they are educated with fome care. The features and outlines of their faces are European; but the complexion, character, and mode of life, approach more to thofe of the native inhabitants of Java. A pale laugh overthrows the countenance. In their own houses, they drefs like their flaves, with a long red chequered cotton gown defcending to the ankles, with large wide fweaps. They wear no head-dress, but plait their hair, and fatten it with a fliver boufkin on the top of the head. The colour of their hair is almost universally black; they anoint it with the oil of the cocoa-nut, and adorn it with chaplets of flowers. When they go abroad, and particularly to their evening parties, they drefs magnificently in gold and silver flangled muffin robes, with a profuion of jewels in their hair, which is worn without powder. They never attempt to mould or regulate their shape by any foreign idea of elegance, or any fandard of fashion; and, therefore, exhibit a striking contrast to the Dutch ladies. Evcry native lady is constantly attended by a female flave, who fits at the feet of her miftrefs on the floor, holding her gold or silver box, the compartments of which contain arocoa-nut, cardamon seeds, pepper, tobacco, and flaked lime; all which mixed together in due proportions, and rolled within a leaf of helot, constitute a maiftery of a pungent tafte, that is in general use. In public affembles, when the ladies are accommodated with heat, they retire to change their draps, and return, without ceremony, in a more light and lofe attire. Their example is followed by the gentlemen, who appear in white jackets, sometimes adorned with diamond buttons. The elderly gentlemen lay aside their wigs, and put on night-caps. The members of the government, except on thefe occasions, appear abroad in crimson velvet; their carriages are distinguished by peculiar ornaments; and they receive homage from others not of their rank. One of the gates of the city is opened only to let them pafs. The Indian women marry young, generally at twelve or thirteen years of age; they have feldom many children, and they are old women at thirty. They are remarkably fond of bathing and ablutions; and use for this purpofe a large tub containing three hogsheads of water, in which they immerfe the whole body at laft twice a week; and some do this in the morning, in fome of the running dreams out of the city. They manifest a moft exceffive jealoufy both of their husbands and of their female flaves; and when they difcover the lighteft fimilarity, punifh the latter with a variety of tortures; and of the former they avenge themselves in kind. The coches used at Batavia are fmall and light, and for keeping thefe a yearly tax is paid to the company. Services of a domestic or mental kind are chiefly performed at Batavia by flaves. Three thoufand of both fexes are annually brought thither from the coast of Malabar, Bengal, Sumatra, and other parts; but in the greatest number from Celebes. Their treatment is in general mild and gentle, though fome infinuates of barbarity and inhumanity occur. They are not forced to exceffive labour, and they are allowed fufficient fufTenance. However, many of the males, who had formerly, perhaps, led an independent life before they were made captives in war, have taken offence against their masters upon flight occasions, and wrecked their vengeance by affiflation. To the apprehenfion of such an event is ascribed the preference given at Batavia to female flaves, for every fervice to which they can be applied; and therefore the number of thofe that is purfued far exceeds that of the other fex. The flaves that are determined on revenge, often fwear, for the purpose of acquiring artificial courage, an extraordinary dose of opium, and forth, becoming frantic as well as desperate, they not only lib the objects of their hatred, but sadly doth to attaick in like manner every perfon they meet. till self-preservation renders it necessary to defroy them. They are laid in that flate to be "running a muck;" so called because, during their frenzy, they continually cry out, "amok! amok!" which signifies "kill! kill!" and their fury has been erroneously ascribed to opium, whereas in reality it is the effect of unruly passion. Influences of it are not more common among fages than among free natives of the country, who in the anguish for losing their money, effects, and sometimes their families, at gaming, to which they are violently addicted, or under the urgency of some other passion or misfortune, have recourse to the fame remedy, with the fame fatal effects. A fondness for play, and also for opium, is not uncommon among the Chinese also at Batavia; but by habits of restraint and moderation they are prevented from falling into the fame frantic exceffes. The Chinese at Batavia are accustomed to keep gaming-houses, which are the means of seduction and ruin to the greatest part of the slaves in the city; and these pelfs of society are under the protection of the municipal government, the officers of which pay to the company, as a consideration for the profits accruing from them, a monthly contribution.
The chief government of Batavia, and of all the chief offices of the Dutch East India Company in Asia, is vested in the council of India, at the head of which is the governor-general, who resides at a large mansion near Batavia, possessing unbounded power, affording a state, and exacting tokens of respect, much greater than any European monarch claims. The next in rank is the director-general, who is the eldest councillor of India; and to him are entrusted the direction and control of the trade of the company throughout all India, and to Europe. Next in order follow the five ordinary and nine extraordinary councillors of India.

To the servants of the company justice is administered by an all-mighty council of judges, independent of the council of India, and consisting of a president, eight ordinary members, and two adjutants, taken from the company's servants. The citizens and free merchants of India, who are not in the company's service, are amenable to a separate municipal court of justice, called the board of scheepers or aldermen, eight in number, with a president who is a member of the council of India.

The punishments inflicted at Batavia are exceedingly severe, especially such as are inflicted upon the Indians; of these the chief, and the most terrible, is IMPALMENT. For taking alive these slaves who are guilty of the acts of murder called "mucks," the officers of justice are provided with a pole ten or twelve feet in length, at the end of which is a kind of fork, made of two pieces of wood three feet long, which are furnished with sharp iron spikes; this he determination the object whom they wish to apprehend, and in his frenzy he runs into it, and is thus taken. If he happen to be mortally wounded, he is immediately broken alive upon the wheel, without any form of trial, in the presence of two or three of the councillors of justice.

The orphan-chamber at Batavia serves for the whole of the Dutch possessions in India; and the board consists of a president, who is a councillor of India, and five regents, who are appointed by the council of India, with subordinate clerks. There are several other courts or boards; as the commissioners of dykes and sluices, those of bankruptcies, a court of common pleas, a board of control over marriages, and several others.

The establishment of regular troops at Batavia, according to the report of captain Parish, cited by Sir George Staunton, consists of 1,200 Europeans, of whom 500 are artillery, and the rest infantry. But as this number cannot be maintained complete in this unhealthy climate, 300 natives were employed, and thus the establishment of European regulars was reduced to 700. Three hundred volunteers of the town are also formed into two companies, but not disciplined. The irregulars are very numerous, consisting of enrolled natives of Java, who have never been emboldened, and of Chinese, whom the jealousy of the Dutch allows to be armed only with lances. This establishment appears too small for any efficient resistance. Although every man who settles at Batavia must take up arms in its defense, it is acknowledged by one of the councilors of the Indies, that their chief dependence was on the havoc which the climate was likely to make amongst the enemy's forces. The chief protection to their ill-armed велелки lying in this port, is afforded by the fortified island of Sachust, which is well situated to command the channel that forms the principal passage into the road.

The climate of Batavia is regularly unhealthy, and has proved the occasion of disease and of death to many of the Dutch settlers, and other Europeans who have tranquilly visited this place. The city is situated in the midst of swamps and devastated ponds, where proceeds every morning a collection of pestilential vapors, whenever the sea-breeze sets and blows over this marshes. The meridian sun rises from the shadowy and muddy canals which intersect the town, deludious mist rises into the air; and the trees, with which the quays and streets are crowded, impede the course of the air, by which the putrid effluvia would in some degree be diluted. Besides the motions circumflam of a bad kind peculiar to this place, the sudden transition from a cold northern region to the middle of the torrid zone, without the adoption of those habits that are requisite in the latter, will render the human frame more liable to be affected by any causes of disease. Hence it happens that preventive medicines are taken almost as regularly as food, and every body expects the returns of sickness, as we do the seashell of the year. There are few examples of druggists who remain long in Batavia without being attacked by fever, which is the general denomination in that place for every kind of illness. The disorder at first is commonly a tertian ague, which after two or three paroxysms becomes a double tertian, and then a continued remittent that frequently carries off the patient in a short time. The Peruvian bark is seldom prescribed in any stage of the disease, or it is given in such small quantities as to be productive of little benefit. The chief, or rather the sole medicine administered, is a solution of opium in spirit of wine. It is supposèd, that of the Europeans of all classes who come to settle in Batavia, not always half the number survives the year. The place resembles in that respect a field of battle, or a town iniegel. The frequency of deaths renders familiar the mention of them; and little signs of emotion or surplise are manifested, on hearing that the companion of yesterday is today no more. When an acquaintance is said to be dead, the common reflection is, "Well, I owed me nothing;" or, I must get my money of his executors." It appears by a calculation, that the company loses, in general, every year, full one-fifth of its servants. It is observed, however, that this climate is not so fatal to the female Europeans as to the other sex. They seldom expose themselves to the heat of the sun, make frequent use of the cold bath, and live more temperately than the men; and, for these reasons, they suffer less from the insalubrity of the climate. In the lower town, on the north side, the mortality is greater, where uninhabited hovels contract a fatal infectious air, than in the other parts of the city that are more fully inhabited. On this account, people not only leave the lower town, but abandon the city altogether, and reside in gardens without the walls, and at a remote distance as their employment will allow. This kind of migration increases from year to year, and will probably, in the lapse of time, produce the total abandonment and ruin of Batavia. The most tolerable season here is from March or April to November, when the rains begin, which last the first of the year. The sea-breeze sets in about ten o'clock in the morning, and continues till four or five in the afternoon; it becomes then calm till seven or eight, when the land breeze commences, and continues at intervals till day break, followed by a calm for the remaining hours of twenty-four. The heat of the weather at Batavia is not so excessive in some other parts of the east. From July to November, Stavinson observed, that his thermometer, which hung in the shade in the open air, floated generally between 84 and 90 degrees of Fahrenheit's scale, in the hottest part of the day; once indeed the thermometer rose to 92°; in the morning, it seldom fell lower than 70°. The barometer scarcely ever varies from the mean height. Sir George Staunton, who

Most merchants' goods are estimated at Batavia by "pieces" of 1/25 pounds; or according to Riccoud, 1385 pounds Amsterdam weight; and their pieces are divided into 100 "carats," each weighing 1 pound. Rice and other grain are measured by "coy Yang," which differ in weight; but when received by the company at Java, they must weigh 3,500 pounds. They are shipped to Batavia for 3,250 pounds, and landed there for 3,500 pounds; at the out-factories, they are dispatched for 3,200 pounds, unladen for 3,150 pounds, and delivered for consumption at the out-factories for 3,000 pounds; so that every coy Yang of 500 pounds in weight. This deficiency is an allowance made to the company's tenants who have the management of the rice. Sugar is taken by "cassiers" of 3 pieces, or 375 pounds net, the goods being about 420 or 430 pounds. The "ginting" is a small rice measure of 133 pounds. Every bag of coffee shipped from Batavia to Holland weighs 251, and a hale of cinnamon 80 pounds.

The bay and harbour of Batavia are excellently adapted to the commercial navigation that is carried on at this place. A circular range of fifteen islands protects the road from any heavy swell, and renders it a safe place of anchorage for ships; and it is large enough to contain all those that double the cape of Good Hope, as well as the Chinese junks and other trading vessels of the country. The names of the islands are, Onrust, de Kuiper, which are the innermost, and within flight of the city; Purmerend, Engels Onrust, Rotterdam, Schiedam, Middelburg, Amsterdam, Horn, Harlem, Edam, Enkhuizen, Aikmaer, Leyden, and Vader Smit. The company make use of only four of these lands, viz., Onrust, de Kuiper, or Cooper's side, Purmerend, and Edam; which lie at the boom, which crosses the bay below the town, all vessels pay toll. The sea-breeze, which rises every morning at ten, serves to bring vessels within the bar, and a land-breeze at night carries them out. The observatory formerly erected at Batavia is now neglected; but the Society of Arts and Sciences, founded under the administration of the governor-general De Klerk, still subsists. The 1st volume of its Memoirs was printed at Batavia in 1779. S. lat. 6° 10', E. long. 106° 51' 15".

Batavia, a settlement of America, in New York, at the head of Schoharie creek, about 35 miles from its mouth, and 28 miles west from Albany, and as far north-west of Eltopus.

Batavia, a river of Asia, so called by the Dutch, situated in Carpentaria, on the coast of New Holland.

BATAVIAN REPUBLIC, an appellation given to the United Provinces, after the conquest of them by the French, the exclusion of the stadtholder, and the change of their form of government.

Vol. III.
Toward the close of the year 1794, and the commencement of the following year, the French forces, favoured by the frost of winter, by the discontents that prevailed in the provinces, and the inefficient support afforded to the Dutch by the British troops, took possession of their principal towns; and on the 27th of January 1795, the provincial representatives of the people of Holland assembled, and chose Pierre Paulus for their president. On this occasion, several decrees were immediately passed for the future regulation of the government, and for the deposition of the stadtholder from all his offices. Among these decrees were the following: viz. the sovereignty of the Dutch people, and the declaration of the rights of man—the abolition of the stadtholdership; as all of the offices of admiral and commander-in-chief of the United Provinces, with all their appendages—the release of the citizens and inhabitants of Holland from their oaths to the old constitution—the suppression of the college of the deputy council, and that of the chamber of accounts; and the establishment in their room of a committee of public safety, a committee of military affairs, and a committee of finance—and the recall of the commission of the deputies to the assembly calling itself the States-general. It was also decreed, that the commissioners of the assembly of the provisional representation of Holland should immediately begin their fittings in the hall of the ci-devant States-general, in order to advance the general interests of the people. A treaty of peace and alliance was concluded between the French and Batavian republics, at the Hague, May 16, 1795, in which the French stipulated to restore immediately all the conquered places and countries that belonged to the seven United Provinces; the frontier towns of the generality, such as Maastricht, Venlo, Breda, Bergen-op-Zoom, with their territories, excepted. It was also stipulated that the French, as well as the Batavians, should enjoy, without paying any tolls, the free navigation of the Scheldt, the Rhine, and the Meuse, and all their branches as far as the sea; that the Batavians should pay to the French the expenses of the war which the latter had been compelled to make against the former; that the French republic acknowledged the independence and sovereignty of the Batavian; that an alliance offensive and defensive should be established between both republics; and that either the French or Batavians should conclude peace, or make any other treaty, in which both parties did not participate.

In 1796, the national convention of the Batavian republic made some considerable alterations in matters relating to religion. It was determined, that all the inhabitants of the republic were free to exercise without molestation any mode of public worship whatever to which their opinions might lead them; that there should be no established religion in the republic; that the use of bells in convoking persons to public worship, should be prohibited; and that Jews should be allowed to become citizens of the republic, and empowered to purchase lands in the same manner as other citizens. On the 11th of January 1797, the new plan of the constitution was discussed; and it was decreed, that the Batavian people should elect representatives to execute its sovereignty. It was also resolved, that all citizens born and resident in the republic, and twenty-one years of age, should be invested with the right of voting; and also strangers, after having resided within the republic six years successively. It was also resolved, that the republic should be divided into eleven departments. Towards the close of the year 1797, the French directory issued their mandate for a revolution. The execution of this mandate was intrusted with Charles Le Croix, and the plan of operations for accomplishing it was concerted with the Dutch general Dandels, who was an original mover, and principal agent in the revolution. Accordingly it was effected on the 22d of January 1798. This revolution gave birth to a new form of government in the Batavian republic, which was introduced and established by acts of violence. An assembly, formed by revolutionary deportment and military force, and assuming the name of the constituent assembly of the Batavian people, abolished those provincial divisions, and other administrations, that had been established under the constitution; which was a constitution grounded on principles deemed more popular than those which formed the basis of that which was about to be presented when this revolution took place, and against which a formal protest had been previously made by forty members of the convention; when it was offered to the primary assemblies for their consideration. The people, wearied with continual agitation, and indeed incapable of effectual resistance, accepted this project formed on the model of the French constitution, as the best remedy against further convulsions; and thus Holland sunk for a while into the state of a dependent province, under the protection of Le Croix, the revolutionary delegate of the French directory. The principal articles that constituted the basis of this new government are the following: viz. —The abolition of the division into provinces.—Separation of church and state.—No corporation or society to have rules contrary to the laws of the state.—Exclusion from the right of voting of all the adherents of the Orange family.—The formation of a democratic representative government by means of a legislative body composed of two councils, and a provincial executive directory consisting of five members, having under it the agents of the executive power.—The formation of a new plan of finance, founded upon the relative means of the citizens.—The commissioners of the treasury are to be appointed by the executive power.—Those of the chamber of accounts by the legislative assembly.—The territory of the republic to be divided into a suitable number of departments; and accordingly, the nine provinces were divided into eight departments, the extent of which was measured by the population and the limits formed by the great rivers; these departments were again divided, each into ten circles; and each department was presump that contained 235,000 inhabitants; and the general population of the republic was estimated at a million eight hundred and ninety-two thousand individuals:—The division of three powers, the legislative, the executive, and the judiciary.—The right of individual petition to the citizens.—Revision of the constitution after the expiration of the fifth year:—The oath of hatred to the government of the stadtholder, federalism, aridity, and anarchy, to be taken by all the persons employed by the republic:—No power to have the right of interfering with the banks of circulation in the different towns of the republic:—Institutions for public instruction in arts and sciences: —And alliance with the French republic.

In the year 1801, a new constitution for the government of the Batavian republic, consisting of 108 articles, was introduced. This constitution abolishes the executive directory, and establishes a state directory, consisting of twelve persons, one of whom goes out annually. The legislative body is to consist of 35 members. The territory of the republic is to be divided into eight departments, whose boundaries are to be the same as those of the old provinces. The allowance of the members of the legislative body is to be 4,000 florins. They are to meet twice in the year, and
to fit from the 15th of April to the 16th of June, and from the 15th of October to the 15th of December. The go-
ve rment has the power of commanding them at pleasure.
For further particulars, see Holland, and United Pro-
vinces. By the treaty of peace concluded at Amiens, March 27, 1802, the Batavian republic cedes and guarantees
to his Britannic majesty, in full property and sovereignty,
all the possessions and effects in the island of Ceylon,
which before the war belonged to the republic of the United
Provinces, or to the Dutch East India company.

BATAVIENSIS, in Entomology, a species of Crypto-
ceranus; the head, thorax, wings, and legs of which are

BATAVODURUM, in Ancient Geography, a town of
the Batavi, in the island called after their name. Accord-
ing to Tacitus, the Romans had a bridge in this place, and
the post was defended by a Roman legion, when the Ger-
man, who resorted to the succour of Cerialis, were d-icted
of penetrating into the island; and here they were repelled
after great slaughter, and at length obliged to throw them-
elves precipitately into the river. Some have supposed
that this town was the same with the modern Durafliles;
but others conjecture that it was not on the same side of
the river.

BATAVORUM INSULA, the island of the Batavi, was
formed by the Vahalis or Waal to the south, and a branch
of the Rhine to the north. This left branch, and also the
Vahalis, rejoin afterwards, and form the Mosa or Meuse.
According to Tacitus, the Rhine was divided at its entrance
into Batavia into two rivers; one of which retained its name,
and pursued its course through Germany, till it discharged
itself into the ocean; the other, washing the coast of Gaul,
with a broader and more gentle stream, was called Vahalis,
which on its joining the Mosa, assumed its name. From
this account it seems that the island of the Batavians was
bounded by the Ocean, the Rhine, and the Vahalis. Caesar
extends it to the Mosa; but Pliny's account coincides with
that of Tacitus. It appears, however, that this island was
of greater extent in the time of Tacitus than in that of
Caesar; as Drusus, the father of Germansicus, had by a new
canal conveyed the waters of the Rhine into the ocean at a
considerable distance to the north of the former mouth of
that river. When this island was occupied by the British
habitants of this island. Some historians say, that they had
been removed by the Cimbri and Teutones, when they in-
vaded the Roman territories; and it is not improbable that
the prospect of a more commodious establishment might in-
duce them to abandon a country which was constantly ex-
posed to the inundations of the water that encompassed it.
The Batavi, when driven from their own country by the
Catti, took possession of it, and became a very powerful
people. A part of this country still bears the name of
Batavus, formed from Batavi; and is probably the same with
the ancient *Insula Batavorum." This name, however,
is given only to the eastern part of the island, and is the same
with that which has the river Lek to the north, and Vahal
to the south of the Rhine. Batavorum Oppidum, Batavurg,
a town which seems to have been the Batavorum of Ptolemy,
but different from that of Tacitus. Ptolemy places it upon the Mosa, or
Meuse; and the Batavodurum of Tacitus was more to the north
upon the Rhine.

BATBERGEN, in Geography, a town of Germany, in the
circle of Weiphalia, and bishopric of Olensburg.

BATCHAJOVE, a town of Asia, in Armenia, 90 miles
south of Erivan.

BATCHelor. See Batchelor.

Batchelor's Buttons, in Botany, See Lychnis.

Batchelor's Pear, See Solanum.

Batchelor's River, in Geography, See Batchelor.

BATCHURISCHKOI, a town of Kinha, in the go-

dernment of Archangel, on the east coast of the White Sea;
8 miles north of Archangel.

BARTOLE, or Bateul, a sea-port on the coast of
Malabar, in the peninsula of India, situated between Oure
and Barcolere. The English had a factory here till 1670,
when they were massacred by the natives. It was ceded to
the British by the treaty of 1799. N. lat. 13 deg. 38'; E. long.
74 deg 37'.

BATE, GEORGE, in Biography, born at Maid's Mort-
on, in Buckinghamshire, in 1638, was sent to Oxford at
the age of 14 years, where he soon distinguished himself by
his diligence and application to study; and having made
choice of medicine for his profession, he was admitted to
practice as soon as he had taken his degree of bachelor in
that line. In 1657 he was made doctor in medicine; and
when Charles the First kept his court at Oxford, he was ap-
pointed his physician. Removing soon after to London, he
was elected fellow of the college of physicians, and physician
to the Charter-house; and conforming to the circumstances
of the times, he soon obtained such favour with the ruling
party in the state, that he was sent to Scotland, in 1671,
in conjunction with Dr. Wright, to attend Oliver Cromwell,
then confined there with an intermitting fever, and was ap-
pointed his first physician. This, however, did not prevent
his being made physician to king Charles II. on his acced-
ion to the throne, and being elected fellow of the newly con-
stituted Royal Society. These honors were procured him,
Anthony Wood says, by a report industriously circulated by
his friends, that he had hallowed the death of the protector,
by administering a deleterious medicine; a story, which, if
believed, whatever reward it might otherwise have procured
him, would never have placed him in a confidential post
about the perfon of the lover-ign. He died in 1688, and
was buried in the chancel of All Saints church, at Kinglon
upon Thames, where a monument is erected to the memory
of him and his wife, who died the year before. The only
medical work in which he engaged was in contributing a
part towards a treatise "De Rerum," published by Dr.
Gessner, in 1650. His posthumous works, an apothecary in
London, were published some years after his death, under the
title of "Pharmacopelia Bateana," and
have passed through many editions. He published, in 1649,
"Euenchus matuon superorum in Anglia, finum ac juris
regii et parliamentarii, brevem narrat," 12mo. Paris. A
second part of this work was printed at London, in 1661.
In composing this, he was assisted by papers furnished by
the chancellor Hyde. A third part appeared in 1679,
written by Dr. Skinner. He is also said to be the author

BATE, in Ancient Geography, a village or city of
Greece, in Attica, belonging to the tribe of Zegides,
where relied Abra, the commentator of Calcidias, who wrote
the epics of the Iliad, and Amygmon, to whom Epicurus bequeathed his property.
Steph. Byz.

BATE, or Bateau, in Geography, one of the principal
ports in a district of India, inhabited by a pratical tribe called
Sangarians, on the south coast of the gulf of Cutch. The
other port is Arabmoy.

BATEAH, a town of North America, in the province
of Yucatan, 160 miles S.S.W. of Menda.

BATEAU, in Navigation, a particular kind of boat,
very generally used upon the large rivers and lakes in Ca-
nada. Its bottom is perfectly flat, and each end very sharp.

5 G 2
and exactly similar. The sides are about four feet high; and for the convenience of the rowers, four or five benches are laid across, and sometimes more, according to the length of the bateau. It is a heavy and awkward vessel both for rowing and sailing; but it is preferred to a boat with a keel for two very obvious reasons: first, because it draws less water while it carries a larger burden; and, secondly, because it is much safer in lakes or wide rivers, where tords are frequent. An oar-club awning may be thrown over the widest part of it, and supported by hoops similar to those of a waggon; and thus may be formed a very excellent cabin, which incloses the quarters of the weather, and at the same time allows a view of the beauties of the scenery on each shore.

BATECUMBE, or BADECOURT, William, in *Biography, an eminent mathematician, supped by Bus (De Illust. Angl. Script. An. 1420. p. 784.) to have flourished about the year 1420, in the reign of Henry V.* He studied at Oxford, and made great proficiency in mathematics; which appears from his writings. It is not known where he died. He wrote "De Sphaera concave fabrica et usu," "De Sphaera foliada," "De Opuslatione Arabalibii," and "Conclufiones Sophas," *Biog. Brit.*

BATELEUR, in Græceology, a name given by S. mini and others to Falco *Eucatius* of Lathom, &c.

BATELLO, St. in *Geography,* a town of Italy, in the kingdom of Naples, and province of Calabria Ultra, three miles north of Reggio.

BATEMAN BAY, lies on the south side of point Upright, on the east coast of New Holland, in which are three or four small islands. The north point is in S. lat. 35° 35'.

BATEMAN's Drope, in *Pharmacy,* are the anodyne balsam made with a weaker spirit, so that a larger dose can be taken; they are tinted with aniseed.

BATENBOURG, or Batt'enbour, in * Geography,* a town of the duchy of Gueldres, feated on the north side of the Meuse, nearly opposite to Ruveltein. N. lat. 50° 55'; E. long. 57° 35'.

Bateni, in *Antient Geography,* a people of Asia, placed by Paus and Schmus towards the Oxus and Bactria.

Batenites, a dept of apostles from Mahometanism, diffused over several parts of the East, who professed the same abominable principles with the Ilmicheen and Karmanians. The word signifies Eforerics, or people of inward or hidden light or knowledge. *Sela's Koran.* p. 186.

Batenketos, in *Astronomy,* a star about the third magnitude, in the constellation of Cetus.

Bates, William, in *Biography,* an eminent non-conformist divine, was born in 1635, and educated at Cambridge, where he took his degree of B. A. in 1647. He afterwards became a celebrated preacher among the presbyterians in London. Upon the restoration, he was appointed chaplain to Charles II.; and received a degree of doctor in divinity, by royal mandate from Cambridge. He was one of the commissioners at the Savoy conference for reviewing the liturgy, and one of the disputants on the side of the presbyterians against Dr. Pearson and other episcopalians. He took the oath required of non-conformists by the five-mile act, and was concerned in several unavailing efforts for effecting a comprehension of the dissenters by certain alterations and confessions. Moderate in his temper, and accomplished as a scholar, he was a fit person to be employed for such purposes; and he was always treated with respect by the members of the establishment. He was also much regarded by King William, and Queen Mary frequently perused his writings. Dr. Bates, towards the close of his life, resided at Hackney, where he died in 1699. His works, consisting chiefly of sermons and discourses, were collected after his death, and published in one volume folio. Besides these, a voluminous volume appeared in Svo, consisting of "Sermons on the everlasting Rest of the Saints." He likewise edited a volume of the lives of eminent persons, written in Latin, and entitled, "Vita selectorum aliquot Viarum, qui doctrinae, dignitate, aut pietate inclucrius," Lond. 1681, 470. The style of Dr. Bates has been commended for its elegance; and he appears to have read many books in polite literature, as well as in theology. *Biog. Brit.*

Bates, Joshua, Esq., late commissioner of customs, was born at Halifax, in Yorkshire, where he began his school education under the celebrated Dr. Ogden, with whom he remained till the doctor returned to reside at Cambridge. During this time he received the rudiments of music from Mr. Hartley, the organist of Rochdale. When Dr. Ogden quitted Halifax, Bates was removed to the school of Manchester, under Mr. Parnell; and it was there, as he has frequently told his friends, that the grand style of organ-playing, in which he so excellently excelled, was taught him by the performance of old Wainwright on the organ in the collegiate church. While he remained at Manchester, he had made such a proficiency in music as to be able frequently to execute for his old master Hartley, when he accidentally called him away from Rochdale.

Bates, on quitting that seminary, was removed to the foundation at Eton; but there his progress in music received a considerable check, and was in danger of being totally stopped; for it was contrary to the rules of that society for any of the boys on the foundation to be permitted the use of musical instruments. In this state of musical privation Bates remained some months, and had no other means of practising than by playing on imaginary keys on the table, which for a considerable time was his custom every day. At length, having by chance had an opportunity of touching the college organ, his talents for music were reported to Mr. George Graham, one of the affianced suitors, who, having a harpsichord, invited him to his rooms; and finding what an extraordinary performer he was, obtained permission from him to procure his musical studies, accommodated him with the use of his harpsichord, and procured him liberty to play on the college organ at his leisure hours.

When he went to Cambridge, the vacancies for King's college were so few, that he was in danger of being superannuated, and was actually entered at Christ's college, where, while he was a member, two of the university scholarships became vacant, and he declared himself a candidate. It proved on this occasion a fortunate circumstance, that he had not gone off to King's; for as Dr. Heath and Mr. Keate, both of King's college, and his seniors, were candidates, the custom of that college would not have permitted a junior to become a candidate. But though he was now a member of Christ's, that circumstance did not prevent his being a candidate for a university scholarship, or the examination which is considered as the most severe of any classical examination in the university of Cambridge. Some of the most distinguished under-graduates were at this time candidates; and after an examination of several days, Zouch of Trinity, and Bates, were elected.

This success established his literary character in the university as high as his musical had been before; and soon after, as the term of superannuation was expired, a vacancy happening at King's, he was admitted a scholar, and
in three years, fellow. The regularity of his conduct, during his scholarship, recommended him so much to provost Sumner, that he was appointed tutor to the college soon after his admission as fellow. While he was in this situation, among his private pupils he had not only students of his own college, but the present lord Bolton, and Mr. Coke the traveller, both then scholars of King’s, were his private pupils; as was the Hon. William Augustus Montagu of Trinity college, second son of the earl of Sandwich. This produced a connexion with that nobleman, which ended in his lordship’s tempting him to resign his fellowship, and reside with him at the admittance in the capacity of private secretary.

Few dilettanti musicians have ever acquired or deserved more fame for their knowledge in music, judgement, and experience in its effects, and abilities in conducting a complete orchestra and numerous band of singers, than Mr. Bates, who, at the university of Cambridge, distinguished himself as a fine performer on the harpsichord, as well as a zatulous votary of the works of Handel; and as long as he remained at college, he performed the part of a Conspicuous at all public and private concerts. It may perhaps not be thought unworthy of notice here, that at this time (about the middle of the last century), the university of Cambridge was in possession of four very extraordinary dilettanti musicians; Dr. Smith, master of Trinity college, for the theory of sound; the Rev. Thomas Twining, an admirable performer and leader on the violin, and an excellent judge of every species of music; the late worthy and ingenuous Mr. Lobb of Peterhouse, the most correct and certain judge men on the harpsichord or organ with whole performance we have been acquainted; and Mr. Bates for his masterly performance on keyed instruments, and abilities in conducting a band. There being at this time no very able professor in the university, these gentlemen regulated and performed at all public and private concerts during their residence in college.

No one stood higher in character, or was more counted in society, while at Cambridge, by persons of all ages than Mr. Bates; in particular by the late Dr. Smith, the master of Trinity college, with whom he spent most of his evenings, and who, at his death, left him a legacy.

Before he quitted the university, an organ was built for the church of his native place, Halifax; and determining that it should be opened with eclat, he, for the first time that any oratorio had been performed north of Trent, attended. With the affiance of the Rev. Mr. Allott, of Kirkleveton, who had trained up the country people in his parish to sing choruses in a very superior style, and with the addition of Bates’s own exertions, with the singers of Halifax, the choruses were performed with a precision that astonished every one; and it was universally acknowledged, by the best judges, that the Messiah had never been so well performed. The first violin, on this occasion, was performed by the celebrated Dr. Hericel, the almoner; and his profession being then music, he was immediately elected organist.

It was the successes of this undertaking that inspired the late commissioner with the idea of reforming the compositions of old masters from oblivion, by having them executed by a numerous and select band of vocal and instrumental performers; and after being settled in London as private secretary to lord Sandwich, he had an opportunity of communicating his plan to persons of the first distinction, and the establishment of the Concert of Ancient Music in Tottenham street was the consequence, being formed and executed entirely under Mr. Bates’s direction: and as many of the works of Handel, which had not been performed for many years, and never so well as at this establishment, were revived, the number of that truly great, and often fulminating composer’s admirers was much increased.

His majesty, a constant and steady patron and protector of the works of Handel, soon after the establishment of this concert, graciously condescended to become a subscriber; and together with him retired to the prince’s condescend to attend the several performances. The nobility and gentry, who were enrolled among the original subscribers to this respectable institution, have been likewise steadily in their patronage and attendance. And it is now (1802), from the splendor and celebrity of its admirable performances, in higher public favour, than at any former period of its establishment.

After remaining some years with the earl of Sandwich at the admittance, Mr. Bates was appointed commissioner of the virtualline office; and soon after, he married his celebrated pupil, Miss Harrop, who had been educated under his eye from his first arrival in London; and whose seraphic voice, and disposition for music, he so highly cultivated, as to render her one of the most enchanting singers which this or perhaps any country ever produced.

The virtualline office on Tower hill now became the receptacle of performers of the highest quality; and as his residence there, was planned that most magnificently musical performance, the Commemoration of Handel in Westminster abbey and the Pantheon, which was conducted by Mr. Bates in a manner never to be forgotten by those who had the happiness of being present. The great splendor and fecules of this commemoration will unit the name of commissioner Bates with the name of Handel, as long as such a memorable event shall remain in the records of the musical art. And the performance of Mrs. Bates, particularly in the pathetic songs of Handel, has rendered it so difficult for her successor at the concert of ancient music, to satisfy the old subscribers in such songs as she used to perform there, that something will always be wanting to complete their happiness.

Soon after the commemoration, Mr. Bates was promoted to a seat at the board of censors, but previously to his quitting the virtualline office, having officiously experienced the difficulties with which the capital of the kingdom often labours under for want of flour, he projected the plan of the Albion Mills; on the success of which he was so sanguine, that he ventured his whole fortune, and even that of his wife, in the capital stock of that company, to the amount of 10,000l. By the configuration which happened to this building, he was completely ruined. His whole fortune was not only lost in the company, but his credit for a large part of the stock in hand, which was all consumed by the fire; so that he was totally bereaved of the means of making any provision for his family, and of guarding against the vicissitudes to which humanity is subject. He submitted to this event with dignity and fortitude; but the circumstance of having involved his wife in the ruin, and sacrificed her professional acquirements without her approbation, preyed so continually on his mind, as at length to produce a complaint in his head, which finally proved fatal, and brought him to the grave, the 8th of June 1799, at the age of 59.

BATESON, Thomas, an English Madrigalist of the beginning of the seventeenth century, not devoid of merit as a vocal composer. He was organist of the cathedral of Chelster in 1600. Ant. Wood says, that he was a performer esteemed very eminent in his profession, especially after the publication of his English madrigals to three, four, five; and six voices. About 1648, he became organist and master of the children of the cathedral church of the Blessed Trinity in Dublin; and in the university of that city, he obtained the degree of bachelor of music.

BATS-
BATH.

BAT-FOWLING, a method of catching birds in the night, by lighting some straw or torches near the place where they are at roost: for, upon besting them up, they fly to the flames, where being anayed they are easily caught in nets, or beat down with bushes fixed to the end of poles, &c.

BATGAN, or B'HATGAN, in Geography, a city of Hindostan, fruite in the extensive plain of the kingdom of Nepal or Nepaul, to the east of Loll Pattan; and 10 miles south of Catmandu, is composed of Nepali. It contains about 12,000 families, extends towards the east to the distance of five or six day's journey, and borders upon another nation, also independent, called Ciratas, who profess no religion. In 1769, the king of Gorkha took possession by force of the city of Batgan. See Father Giuseppe's account of the kingdom of Nepal in Asiatic Researches, vol. I. p. 328.

N. lat. 28° E. long. 83° 12' N.

BATH, a city of Somersetshire in England, is situated in N. lat. 51° 22' 30" W. long. 2° 21' 36", at the distance of 107 miles west of London, and 12 miles from Bristol. This ancient and elegant city is singularly favoured by nature and art; whole joint co-operations have conspired to give it importance and celebrity. The beauty and peculiarity of its situation are perhaps unequalled by any town in England. Planted originally in the bottom of a deep and narrow valley, where its hot waters boil up, it continued for ages to be confined to the dimensions which the Romans had first marked out; and till within the last century, the ancient Roman walls (inclosing a space of about fifty acres) formed the boundaries of Bath. But the fashion and celebrity which it latterly obtained, induced many builders and speculators to extend the streets in all directions, by additional houses, which were incessantly occupied upon completion. Built of the fine siltic, or granulated egg-like freestone, which forms the bafis of the surrounding hills, the houses are remarkable for their exterior neatness and splendour, and being raised over the sides of the broad acclivity of Lansdown (which rises to the north) in irregular groups of streets, squares, parades, circuits, and crescents, they present to the eye an appearance equally singular, magnificent, and beautiful. Nothing, indeed, can be more picturesque than the views of this city from various situations on the surrounding eminences; where houses rise above houses in progressive order, and the more elevated seem to look down with proud superiority on the no less elegant and extant houses below.

Bath, Ancient History of. Various names have been given to this city at different periods. Its British appellation was Caer-Baddon. In Latin, it was called Aquae Solis, Fontes Calid, Achaamannum, Thermae, Badonia, &c. and in Saxon, Acemanes-ceap, Acemanes-beep, Leotbana, &c. Most of these names refer to its situation, and its springs or baths. The origin of this place as a littlement or town, is lost in the lapse of ages; and its early history is enveloped in legendary tales and monkish fables. The strange story of Bladud and his leprous pigs is dissevered by all rational thinkers, though it formed a part of the creed of the Bath citizens till within the last fifty years. But the present generation (observes Mr. Warner) are wiser and more prudent than their forefathers, and rather attentive to the value of the springs than their origin, have at length forgotten the antiquity of their discovery; in the agreeable contemplation of the large rents which they throw into the corporation chests.

That Bath was one of the principal, if not the most considerable, of the Roman stations in England, is satisfactorily proved by the many architectural and military antiquities which have been found within its precincts. It is probable that if Bath was not originally built by the Romans, it was at least reduced under their power, and embellished by their arts, as early as the middle of the first century; when, in the reign of the emperor Claudius, according to Tacitus, about the year 44, the western and southern parts of this island were completely subdued by Titus Vespasian. Attracted by the medicinal and warm springs which they found here, and which afforded every means of indulging in that prime enjoyment of Roman luxury, the bath, the Roman soldiers fixed in this place one of their principal stations. "Aquae Sulis," the name by which they designated this delightful residence, was soon established as a colony; and of course became entitled to the privilege, which all the Roman colonies enjoyed, of minting its own money. It is to be conjectured also, that a military forge, or college of armours, was erected here for the fabrication of legional arms, under the authority of a Roman government. In the reign of Adrian, about A.D. 118, the first detachment of the second legion, which had been stationed here, was joined by a division of the sixth; and in that of Severus, a part of the twentieth legion, removed from Vienna, or Chelten, had its station in Aquae Sulis, which was then become the most capital city in Roman Britain, and the principal, if not the only, place in this part of the island, for preparing the legional arms and ensigns. The form of the city then constructed, according to that usually affected by the Romans, approached to a parallelogram, swelling out on one side, so as to describe an outline somewhat pentagonal, and stretching in length, from east to west, about 400 yards, and 380 yards in the broadest part from north to south. The wall, which rose upon the outline of the settlement, appears, from sublequent discoveries, to have been twenty feet above ground in height, and in thickness sixty feet at the base, and thirty at the summit. It was strengthened by five towers, rising at the angles; and had four portes, or entrances, facing the cardinal points, which were connected together by two grand streets, dividing the city into four parts, and interfacing each other at the centre.

The place thus fortified and strengthened for security, was next adorned with houses for the officers, temples, and those magnificent baths, the remains of which were discovered, in digging to a considerable depth, in the year 1755. These baths were erected near the centre of the city, between the north and south gates, on the eastern side of the great folk-road. The fridatories, tympanum, fluted columns, cornices, pilasters, and sculptured ornaments, found here, proved that the buildings were constructed from elegant designs, and of similar characters to some structures discovered in Italy and Tivoli. Many altar-sacrifices have also been found here bearing the inscriptions of Dee Sulini Minerva, Dee Sulinis, &c., concerning which many conjectures have been adduced. Mr. Warner affirms the goddess Sulinis to be a local deity, Mr. Lysons affirms that the name is of Gothic origin, whilst Mr. Whitaker more appropriately and happily explains it to be the British characteristic appellation for Minerva as the tutelary goddess of m-ucine, deriving her influence immediately from the sun. This great defoner of heat was denominated Sul in the Celtic language. The ancient baths occupied a space measuring 230 feet in length from east to west, and 120 feet at the broadest part from north to south. (These baths, and remaining fragments, have been particularly described and illustrated by governor Powall and Mr. Warner, in publications expressly on the subject; and the fragments are represented and described by Mr. S. Lysons in a volume lately published.)

The Romans being established here, constructed four of their great military roads to communicate between this place
BATH.

(Aqua Soly,) and the nations of Durocorium (Cirencester), Verulam (Haddington), Ichelais (Iffley), and Abene (Amersham). The conquering Romans having enjoyed the possession of Bath and England for nearly four centuries, at length left the whole island to the possession of the Britons, who were afterwards subdued by the harry Saxon. It was not till the year 577 that Aquae Sulis fell into the hands of the Gallican conquerors, who, under the command of Candia and Cutham, overcame Cirencester, Cirencester, and Bath, at a place called Dyhyam, eight miles from the latter place, and took possession of their respective dominions. Bath now received the privileges of a Saxon burg had its Gerefa or judiciary appointed to it, who presided in the monthly meeting of its citizens, called the burgenote or tolentum; councils instituted for the regulation of the police, and administration of the laws within the burgh. Bath was afterwards taken by Offa, king of Mercia; and during the civil wars and Danish invasions which prevailed in the eighth century, it was torn to pieces and nearly exterminated as a town. During the brilliant reign of Athelstan, this place again rose to consequence; and a mint was established here by the first monarch, who also gave several large donations of estates to Offa's abbey. King Edgar was crowned and inaugurated here, and testified his regard for the place by granting it several privileges. The inhabitants seem to have been fully sensible of the favours conferred on them by this monarch; and according to the statements of Leland they praved for several centuries "in all their ceremonies, for the king's sole; and at Whitsuntide," he states, "there is a king elected every year of the towns men, in the joyful remembrance of king Edgar, and the privileges given to the town by him." During the Danish dominion in England, the mints of Bath continued to be worked, and several coins of Canute the Great, struck here, are still remaining in some select cabinets.

The Norman conquest had produced much general evil to the country; and Bath, with several other cities, experienced, in consequence of its great deterioration. But this was partial and light, compared to the miseries which happened to Rufus's reign; when in the insurrection raised by Odo bishop of Bayeaux, Geoffrey bishop of Conflance, and Robert de Mowbray; the two latter took the place by assault, and, in the spirit of the times, delivered it over to plunder and burning.

Bath was indebted for its restoration to John de Villula; who purchased it of Rufus, in 1095, for 500 marks, and obtained permission to remove the的照片 feat from Wells hither. He rebuilt the city, erected a new monastery upon the ruins of the old one, and united the bishopric to this institution. Thus reinvaded, Bath gradually increased its monastic possessions, in consequence of the munificence of monarchs and private persons; but the sweeping dissolution of Henry VIII. drove the monks from its monastery, when the abbey-house, with its lands, &c. was granted to private individuals.

The citizens of Bath returned members to the English parliament as early as the 26th of Edw. I. and waited were regularly sent them for the same purpose every time parliament was summoned to meet. But as those privileges were attended with heavy charges on the burgesses, who generally paid the expenses of their members, the city was not represented during the 18th and 2d years of Edward II. It now sends two members, who are elected by the body corporate, consisting of thirty-one persons. The government of Bath was originally vested in a sheriff; and the first that appears to have borne this office was Elfred, who is said to have been a great benefactor to the city, and died A.D. 907. It had afterwards a provost or bailiff. Its first charters were confirmed by king Edward III., Richard II., Henry V., and Henry VI. Queen Elizabeth, in the 22d year of her reign, granted the city a new charter, declaring it to be a sole city of itself, and the citizens to be a body corporate and politic, by the name of mayor, aldermen, and citizens of the city of Bath. This charter was renewed in 1754, when two additional franchises were granted the city and under that charter the corporation derive their authority, power, and rights.

The commerce of this city, abridged from the expences of fashionable company, is incomparably, nor is there any manufactory deserving particular notice. Bath was formerly distinguished for its clothing trade; and at the time of the restoration, it is said, there were no less than sixty broad-cloth looms used in the parish of St. Michael.

The river Avon, which winds round the southern part of this city, was made navigable by an act of parliament in the 12th of queen Anne; and the first barge, laden with deals, pig-lead, and meal, was brought here December 13th, 1727.

In the early part of the civil wars, this city was garrisoned for Charles I., and the sum of 7000l. is said to have been expended upon its fortifications; notwithstanding which, it was quickly surrendered to the enemy, and was made one of the principal posts for the parliament's forces. Sir William Waller lay here for a considerable time with his whole army, making forays into the country, and invading together all the disaffected from the neighbouring clothing towns and villages. But after the battle of Roundway-down, July 13, 1643, in which Waller was defeated, and the withdrawal of the garrison for the reinforcement of Bristol, the king's troops took possession of the city.

Having detailed a few particulars relating to the early history of Bath, we proceed to a brief description of its principal public structures, and other prominent objects which characterize this fashionable place. The Public Baths are in four numbers, besides two private baths. These are all constructed with particular attention to the convenience and accommodation of invalid bathers; and the laws and regulations are very equitable and fair. (For an analysis of the hot waters of Bath, and an account of their medicinal powers, vide Dr. Gibbes's Treatise on the Bath Waters.)

The King's Bath is supposed to be so denominated from some of the Saxon kings having made this city their residence. It is situated to the west of the abbey church, and forms a parallelogram, 65 feet 10 inches in length, and 43 feet 10 inches in breadth; the bottom of which is 12 feet below the surface of the ground. The spring or main source is from the centre, which is covered with a large leaden reservoir, to restrain its rapid motion, and to diffuse the water more equally, both for bathing and drinking. There are also two commodious rooms with pipes, fire-places, and other conveniences for the bathers. This bath fills in nine hours.

The Queen's Bath, which receives its waters from the former, forms a square of about 25 feet in diameter. The Cross Bath forms a hardstone termination to Bath-street, and is a very elegant building, constructed after a plan of Mr. Baldwin's; its shape is triangular. The Hot Bath is erected to the south-west of the latter, and is so called from the superior heat of its water; this also forms a parallelogram, and is perfectly convenient with respect to an open bath, private baths, dry pump, and dressing rooms. Certain regulations are promulgated respecting these baths and the persons belonging to them; as well as particular fees for every process of bathing, pumping, &c. Adjoining to the king's bath,
in Staflestreet, are some new private baths, which were
erected by Mr. Baldwin in 1788. These baths belong to the
Corporation. There are also the private baths, called the duke
of Kington's, or the Abbey baths, belonging to lord New-
ark, and in the occupation of Mr. Sloper. See Bath
Water.

**Bath. Public Buildings.** The Guildhall is a very handsome
structure, built after a design of Mr. Baldwin, and contains
a number of useful and convenient rooms for public
business. In the council-room, one of the most elegant of the
king in England, are portraits of the king and queen, the
late prince and princess of Wales, and the late earl's Chatham
and Camden. The Pump-room was constructed, by the
same architect, in the year 1795; its length is 85 feet,
including the recesses at the ends; in breadth 45 feet, and 34
feet in height. The inside is tinted with Corinthian
three-quarter columns; and lighted by a range of large
windows below, and of half ones above. Here is a marble
statue of Richard Neif, Esq, the author of the Grammar
of Bath; a gentleman to whom this city is principally indebted
for its fashionable celebrity. The pump is held under a
beneficial sale from the corporation for three years, the rent
being 50 guineas, exclusive of taxes; which, however, is
sufficiently low to enable the缴纳 to lay up 1200/.
1795, or 1500/ during the term. Most of the elegance of street-
building in Bath is owing to the late Mr. Wou; who
commenced his operations with spirit, and conducted them
with taste. To him the city is indebted for Queen-square;
the northern side of which presents a chaste and neat range
of structures, decorated with all the ornaments of the Cori-
thian order.

The Circus is of his designing; here the houses parake of
the three orders, Doric, Ionic, and Corinthian, highly
ornamented. To the grandeur of his design, the North
and South Parade bear ample testimony; as do several
streets stretching to the northern end of the old city, which
are near racy by judgment and execution. Subsequent ar-
chitects have followed Mr. Wood's example, and hence arises
a profusion of new squares, crescents, parades, and streets;
thus increasing Bath to fix times its original size; and the
beauty of the city is equal to its extent.

The new assembly rooms are the most elegant of the kind
in Europe; these were built by Mr. John Wood in 1771,
at an expense of 20,000/. The ball-room is 105 feet 8 inches
long, 42 feet 8 inches wide, and 43 feet 6 inches high; the
other parts of the building are composed of the octagon
room, the tea room, and the card-room, all of equal beauty.
The regulations to preserve order and decorum in these rooms
are simple and satisfactory. The lower rooms, near the
north parade, have a convenient suite of apartments appro-
rated to the elegance of the place; and here are to be seen
the original regulations by Mr. Nah, which he wrote for
the purpose of inducing politeness and urbanity to a system.
A neat Italian theatre was erected in Orchard-street by the late
John Palmer, Esq, who obtained a patent for dramatic enter-
tainments in 1768; and here plays are performed on Tues-
days, Thursdays, and Saturdays. Sydney gardens are laid
out in a very pleasant and elegant style, for the purpose of
evening promenades: where gaiety and public music and
fashioning are given similar to the entertainments at Vauxhall
gardens of London.

**Hospitals, &c.** Built ngs and institutions of this nature form
a striking feature of Bath; and no place in the realm, accord-
ing to its size, exhibits so many foundations for the extirpa-
tion of disease and wretchedness, for the support of the poor,
and the instruction of the ignorant. The general hospital, from
the munificence of its plan, is an institution open for all
the sick poor in the united kingdom, who labour under dis
eases to which the hot waters of Bath particularly apply, with
an exception to those persons inhabiting the city, who have
the waters at their own houses for a small expense. Mr. Nah
had the honour of suggesting the idea for its foundation, in
1715, and the first stone was laid in 1738. St. John's hos-
pital, originally founded by Reginald Fitz Jofelin in 1182,
and the chapel attached to it, stand near the crofs bath, and
were built in 1728, upon the site of an old structure for the
accommodation of sick infirm men and women. St. Ca-
tharine's hospital, called also the Black alms and Bimberries,
is another asylum for ten poor persons. Bellot's hospital
entertains twelve poor men and women, who have each an
apartment, the liberty of bathing, and a small weekly allow-
ance. The Bath city Dispensary and Almshouse is equally
open to the inhabitants and strangers in cases of physical
and surgical emergency; and is a most excellent institu-
tion. The Charity hospital is appropriated to paupers who have
been injured by accidents. The Puerperal, or child-bed char-
ity, is another benevolent institution, whose objects are
explained by its name.

Bath has, besides these establishments, a public grammar
school, charity and Sunday schools, with many humane and
scientific societies. The principal of these are, the drangers'
The first is established and conducted on the most benevolent
principles of universal philanthropy; and the only recom-
mandation for relief, is a sufficient proof of evident distress.
The second was established by Mr. Edmund Rack in 1777,
for the encouragement of agriculture, arts, manufactures,
and commerce; and from the judicious management of its
founder, and late secretary Mr. W. Matthews, it has ac-
quired some celebrity, and proved of extensive utility. The
philosophical society was established in the year 1799, by
some respectable literary characters at Bath, upon a plan
somewhat similar to that at Manchester, for the promotion of
science and the diffusion of knowledge.

**Parishes.** Bath is divided into the parishes of St. Peter
and St. Paul, St. James, St. Michael, and Walcot. Bathwick,
thought connected by Pulteney bridge, and consisting of a
great number of half-dome houses, is cut of the jurisdiction
of the city. Each of these parishes has its church; and
in that of Walcot are several chapels of ease. Of these the
principal is the Abbey Church, which presents a noble speci-
mum of English architecture. It is built in the form of a crofs,
from the centre of which rises a tower 162 feet high, orna-
mented with beautiful light perforated battlements. The
length of the body from call to wall, is 210 feet, from
north to south, 126; and the breadth of the body and side
niles, 72 feet. The grand entrance at the west is through
a noble arched doorway; and the chaste uniformity, propor-
tion, and harmony in the structure of the interior of this
stately building, powerfully arrests the attention of the be-
holder. The west window is of extreme richness, and the
whole of this front displays a representation of allegorical
carvings, not usually met with. The roof, consisting of two
parts, the nave and the choir, is equally remarkable; the
ribs which compose its tracery being the only solid work, the
intermediate spaces having being originally left open, and af-
terwards fill'd up with bath and plaster. The windows are all
large, of admirable and nearly uniform construction; this has
occasioned the church to be called "The Lantern of Eng-
land." A profusion of marble monuments ornament, or rather
crowd up, the inside; among which may be noticed those
of bishop Montague, Queen, beau Nash, lady Millier, and sir

William
The分析 of Bath water has been the cause of much controversy among chemists, but it seems now to be well understood. To the taste it is neither biting, nor acid, nor alkaline, nor impure; it is simply hot and chalybeate; and it is only marketable that the chalybeate taste is entirely lost as soon as the water cools, before any sensible precipitation of the iron takes place. The actual quantity of the iron is so minute as never to have been climaxed with any accuracy: probably a quarter of a grain in a gallon is an ample allowance, a quantity too small as only to be perceptible to the taste when fresh drawn and hot.

Bath water contains no other ingredients of any importance. It is hard, and holds some calcareous earth in solution, and (as Dr. Gibbs has discovered) a portion of silica. It is perfectly free from sulphur. A considerable quantity of azotic gasses rise from the earth along with the water, and a certain portion is held by it in solution or rather weak affinity. Of carbonate acid it only contains about \( \frac{1}{4} \) of its bulk.

The diseases for which the Bath water has been recommended are very numerous. It has long enjoyed a high celebrity in the cure or relief of gout, chiefly of the stone kind; of rheumatism; paralysis, especially that partial palsy of the limbs induced by rheumatism; and diseases of the urinary organs. When drank freely from the spring (the only time when it pollutes any peculiar virtue), it sometimes ratifies the pulse, cauizes the face to flush, and heats the body very considerably; and hence there are many invalids who cannot bear its operation, or who must be gradually accustomed to it. This heating effect, however, is by no means constant or universal. It often produces a collique state of body and generally keeps the patient periodical and eaily perspirable. Its use as a hot, warm, or tepid bath is fled as extensive and probably important as when taken internally. It has been thought by many that the practice of drinking our Bath waters in Somertershire is not very ancient, and that their ancient use was in bathing; but Dr. Freud endeavours to show the interval use of these waters to have been very early. Dr. Guidot, in whose time this usage revived, and who has given us an historical narrative of these waters, goes no higher for their internal use than the latter end of the sixteenth century. But they appear to have been in use in the thirteenth century. Gilbert, renowned Anglicus, who, according to Bayle, lived about 1270, in the reign of king John, or more probably in that of Edward I., mentions amongst the curiosities of a certain place, a great swelling, &c. by the sulphureous baths: which Dr. Friend underliest the Bath waters; and that the cure was wrought by drinking, not bathing, which had been improper in such a cafe.

Dr. Masegrave makes it probable, that they were referred to in the time of Cæsar; there being found the remains of a statue erected to that general, in gratitude for some benefactions which he had conferred on the place. Some pretend that these waters were in use 800 years before Christ. Phil. Trans. N° 49 346.

The two stated seafons for drinking the Bath waters are spring and fall, though they may be used whenever they are found necessary.

Bath, in Geography, a river of Africa, in the kingdom of Fez, which rises in mount Atlas; and joining the Saba or Sbah, flows into the ocean north of Minamore.

Bath, a country of Virginia, in N. E. America, about 60 miles long and 50 broad. bounded on the east by the country of Augusta; and noted for its medicinal springs, which are hot and cold, near the foot of Jackson's mountain.

Bath, a township of Lincoln county, in the district of Maine, in America, containing 949 inhabitants. It lies on the
BATH.

the west side of Kennebeck river, about 13 miles from Wiscasset, 60 N. E. from Portland, 32 from Hallowell, and 165 N. E. from Boston. N. lat. 43° 49'.

Bath, a thriving town, in Berkley county, in Virginia, seated at the foot of the warm spring mountain. The springs in the vicinity of this town, though less efficacious than the warm springs in Bath county, draw upwards of 1,000 people here, during summer, from various parts of the United States. The county in the environs is agreeably diversified with hills and valleys; the soil rich and well cultivated; 269 miles S. W. from Philadelphia.

Bath, a township of America, in Graffton county, New Hampshire, containing 439 inhabitants; and lying on the east bank of Connecticut river; 35 miles N. E. from N. from Dartmouth college, and 97 N. W. from Portsmouth.

Bath, or Port Bath, an ancient town in Hyde county, North Carolina, on the north side of Tar river, about 24 miles from Pamlico sound, 64 S. by W. from Edenton, and in the port of entry on Tar river. It contains about 12 houses, and is declining. N. lat. 35° 31'. W. long. 77° 15'.

Bath, a village in the county of Renfelaer, New York, pleasantly seated on the east bank of Hudson river, nearly opposite to the river of Albany, at the head of Sloop navigation. A mineral spring has been discovered in this place, and a commodious bathing-house has been erected, at a considerable expense, containing hot, cold, and shower-baths.

Bath, a thriving post-town in Steuben county, New York, containing about 50 houses, situated on the north bank of Conhoacon creek, a northern head-sater of Tioga river, 43° 30' S. E. from Williamsburg, 120 from Niagara, and 221 miles from Hudson city. N. lat. 42° 15'. W. long. 77° 10'.

Bath, a village in the eastern parish of St. Thomas, in the island of Jamaica. It owes its rise and name to a hot spring near it, which is said to be very efficacious in the cure of the dry belly-ache. The sulphureous water flows from a rocky mountain about a mile distant, and is so hot that the hand cannot be held in it.

Bath, balneum, a convenient receptacle of water for persons to wash or plunge in, either for health or pleasure. Baths are either natural or artificial. Natural, again, are either hot or cold. See Mineral Waters.

Baths, Artificial or Medicated. The very accurate imitations of most of the mineral waters for the purpose of drinking which are now met with, have induced some ingenious artists to extend the imitation to larger quantities of water sufficient for the purpose of bathing. The method of performing each will be explained under the article of Water, Mineral.

Of artificial baths some are aqueous, others vapporous, others dry, &c.

Baths, Aqueous, are those prepared from common plants and other substances of emollient, resolvent, and nervous kinds. Aqueous Baths sometimes consist of milk and emollient herbs, with rose-water, &c. when the design is to humectate; at other times of bran and water, when the design is only to cleanse; sometimes again they are made of a decoction of roots and plants, with an addition of fruit of wine, when a person babbles for a great pain or tumor, &c.

In Vappour Baths, the fume or steam of some decoction is received upon the body to promote a perspiration. There are also by some called Bathea Locemen.

Vappour Baths are, when the patient is not plunged into what is prepared for the bath, but only receives its fume upon those parts of his body which require it; as in some distempers of the fundament and womb, where the patient sits and receives the fumes of some proper fomentation, &c. Mrs. Bath, a celebritious author, has published "A Method of constructing Vapour Baths," as to render them of small expense, and of common use in private families. The principles on which this method is founded are, that in the vapour bath the water being applied, not in the state of steam, but, that being solid, is received in the air. Men of spirit is then saturated, the heat of the inclosed air can be maintained in a sufficient degree; and that the room is filled, either metallic ones, being the greatest conductors of heat, are to be avoided in the construction of the vessel containing the vapours, and the lightest and most non-conducting materials used instead of them. The whole apparatus for the vapour-bath is, therefore, reduced to a box, tin pipes wrapped in flannel, and a deal box, with a cotton cover, for the reception of the body and circulation of the vapour.

To these may be added the bagnio, where people are made to sweat by the heat of a room, and pouring on of hot water; after which they generally go into a hot bath, or hagmi. See Bathing.

Baths, Dry, are those made of ashes, salt, sand, flints of leather, and the like.

The ancients had divers ways of sweating by a dry heat, as by the means of a hot sand, foyro rooms, or artificial bagnios, and certain natural hot fumes of the earth, received under a proper arch, or hot-houne, as we learn from Celsus. They had also another kind of bath by molatation, where the body was exposed to the sun for some time, in order to draw forth the superficial moisture from the inward parts: and to this day it is a practice in some nations to cover the body over with horse dung, especially in chronic diseases, to digest and breathe out the humour that causes the distemper. In New England, they make a kind of fls of turp, wherein the sick are shut up to bathe or sweat. Phil. Trans. No 384, p. 150. The same name is sometimes also given to another kind of baths, made of kindled coals, or burning spirit of wine; the patient being placed in a convenient cloche chair for the reception of the fume, which rises and pro. vokes sweat in a plentiful manner: care is here taken to keep the head out, and to secure respiration.

This bath has been found very effectual in removing old obdinate pains in the limbs, and other complaints; and, it is said, will often complete a cure, left unperformed by salivation.

Baths, Metallic, those made of water impregnated with the f binaries of metals. The mud common and useful of this kind are those prepared with the f binaries of iron, which abound with the earthly, saline, and sulphurous sub stance of the metal; and these are of excellent service for strengthening and braceing up the part to which they are applied, and recovering weak and decayed limbs; stopping various kinds of bleeding; and retarding the menstrual and hemorrhoidal flux, where obstructed; in such quantity that they may well be substituted for the natural iron baths.

Adjacent to the fine ting huts where metals are rem from their ore, are to be found large quantities of the flag of copper, antimony, and cobalt, which, assaying with sulfur, vitriolic salt, and an earthly principle, make serviceable baths for strengthening the soft tone of the fibres, and laxing them when they are too full. These baths have likewise a detestive and cleansing virtue; so that, with prudence and due regard to circumstances, they may be used on many occasions. The way of making these artificial baths is, either to take the flags as they come hot from the fur,
BATH.

Bath, Balneum, in Chemistry. In many chemical processes it is the utmost importance both for the facility of the vessels, and the success of the operation, that the application of the necessary heat should be gradual and regulated. This is particularly the case in distillations, and in digestions at a moderate temperature, and whenever globe vessels are employed. Hence the contrivance of baths or internally between the burning fuel and the vessel containing the subj ect of the process, in which the vessels are immersed, and whereby they receive the heat in a regular gradual manner. As fluids heat with more uniformity than solids, they are preferable where only a heat a little inferior to the boiling point of the fluid is required; and they possess this important advantage, that the heat is so kept down by evaporation, that it can never rise beyond the known and given point of boiling. But where as much even as a low red heat is required, no fluid can be employed with any convenience, and recourse must be had to some incom busible solid reduced to powder. A great variety of baths were used by the elder chemists, especially those who were engaged in alchemical pursuits, which were supposed to require long digestions in a very accurately regulated heat; but most of these are now laid aside, and only the following kind of baths are retained.

The water Bath, Balneum Aquae, is of great use in the distillation of volatile oils, of the aromatic part of vegetables, of the finer kinds of aromatic spirits, in evaporating into dryness the solutions of vegetables employed in medicine whose virtue would be lost by any excess of heat, and in many other processes. The apparatus for this bath forms part of the improved alembic (which see, in Plate III. fig. 13. A. of Chemistry); but any vessel full of water, capable of being heated to boiling, and of containing a retort or other vessel, may be used as a water bath. As the utmost heat which any substance immersed in a boiling liquid can acquire thereby, falls short by a few degrees of the temperature of the liquid itself, the heat of a water bath cannot amount to 212°. This is considerably increased, however, by using a strong solution of sea-salt, or any other salt, instead of water; as the boiling point of saturated brine is much higher than that of mere water. This forms the ancient Balneum Maria, Bath of Mary (the Virgin, as some have interpreted the term); but others with more plausibility write Balneum Mariae, sea-salt r, or brine bath.

Mercury, the bubble alloy of bismuth tin, and lead, the atoms, and other metals, have been applied for the purpose of baths, and now and then used, when a higher heat than the hot water bath is required; but the metals are cumbersome by their weight, and expensive, more is dangerous to the bystanders from its evaporation, and they all have the inconvenience of requiring more pressure to be used than the mere weight of the substance which they are to heat, to enable it to be immersed in the melted metal.

Balneum Siccam. This well-known term has been applied to the outdoor bath, in which the vessel to be heated is enclosed in a kind of case filled only with the steam of boiling water. It is small if not quite out of use for chemical purposes, but it forms a valuable implement for the kitchen.

Balneum Acre. Sand bath, of all kinds or chemical baths is that which is used the most extensively. In experimental furnaces, or smaller chemical operations, the vessel to contain the fluid is of card iron, very much in the form of an inverted round hut, of which the hollow part is supported by the projecting rim upon the sides of the furnace, and hangs down over the burning fuel. The flame of which plays round it and gradually heats the vessel which it contains, together with every vessel buried therein. The sand should be of reddening fines, the finest as well as the very coarsest being separated by sifting; for by this means the heat is more gradually distributed. These distillations, which at any part of the process require as much as a low red heat, are usually performed in sand baths, even in manufactures in the great way, as of aqua fortis. Sand, when thoroughly heated, continues hot for a very considerable length of time.

Bath is also used in another sense, to signify the fusion of metallic matters in certain operations; thus, in refining or culminating, the metals are said to be in bath when they are melted.

Baths, the name proper to such public or private edifices as are used for bathing.

The practice of bathing is found among all the nations of antiquity. The people of the East were ever accustomed to it, and have continued the habit to the present time; their methods being perfectly conformable to those of the Greeks and Romans. If we may credit Homer, Moseley, and Thucydides, the first ages of Greece knew no other baths than the rivers, and it was not until the rise of the prince's Nautica, and Helen bathed. Homer (lay the French Encyclopédists) indicates, that in his time private baths of a regular form were in use. Telemaque and Phœdrus, they observe, were conducted to baths of uncommon seats: the most beautiful slaves in the palace bathed them, perfumed them, and adorned them with the handomest garments. But all this is an assumption which the text of their author by no means warrants. The passage alluded to is in the Odyssey, Book x. l. 135.

ξύφω στὴν δαίμονας ερυθρίας ἱππάτισις θερμήν
καλλι χρυσόν νητὶς αργηίαν λιπάσις
ναυτικαὶ.

And the lines which follow plainly show, it was nothing more than a common ablution previous to an entertainment. The Aith s was a kind of v ale occasionally placed upon a tripod.

The Romans, who for a long time bathed in the Tyber, borrowed the idea of artificial baths from the Greeks; their various habits of life and times rendered such accommodations necessary; and, to make short of our relation, all the most splendid and fascinating luxuries of the emperors were...
BATH.

multiplied and brought together in the vast buildings of the
thermae.

The thermae, these prodigious monuments of Roman
maquiiicence, were formed in imitation of the Greek gymna-
sia. In both were assembled all the institutions favourable
to health, all the exercises of the body, all the exercises
which were supposed to relax on the mind, and afford
amusement to the people. Although the name of thermae,
given by the Romans to these edifices, signifies a place
ded to the use of warm-baths, yet the diversity of uses to
to which they were applied will not suffer us to comprise
the whole in a single article. All that concerns the
immediate use of the baths will be found here; but for other
details, we shall refer to
Thermae.

The most complete and beautiful baths were composed of
six principal apartments.

The first was called the apodyterium, where the frequenthers
of the bath undressed; it was furnished with tables to receive
the garments of the bathers, and guards named coriari
to take care of them. This room was also called by the Ro-
mans the frigidarium. All the baths were not furnished
with an apodyterium. Lucan says, that in those which
were without it, the frigidarium was used for the same
purpose. The apodyterium is found neither in the gymnasium
of Vitruvius, nor in the palace described by Lucan. It is
very probable, there was no such apartment in the Greek
gymnasia, and that the frigidarium supplied its place. Pinay
is the only author who mentions it, when describing the
baths of his country house.

The second apartment was the cold-bath: named laconon
by the Greeks, and frigidarium by the Romans. This room
was usually exposed to the north, and served, as we have
just related, the purpose of an apodyterium to such baths as
were without one; of course, it was then the first apartment.

The ancient writers imagined that the frigidarium and
tepidarium were the same; but ancient paintings prove the
contrary.

The third room was the tepidarium. Its principal use was,
by the temperate air it contained, to prevent any bad effects
that might be occasioned by passing too suddenly from the
warm to the cold apartment. In the paintings of the baths
of Titus, this apartment is found between the frigidarium and
the concamerata sudatoria. The tepidarium, according to
historians, joined the frigidarium to the warm bath; and it is
for that reason that Pinay calls it calda media, the middle
room. Galen gives it the same name, and imagines it ac-
quired this appellation on account of its situation in the
centre, but more in its temperature for, says he, this
room was as many degrees colder than the third or warm
bath, as it was warmer than the first or frigidarium. The
frigidarium and tepidarium, however, were more frequented
for the benefit of the air than of their water.

The fourth chamber was that which contained the flo\ve;
and was called laconium, from the name of the oven which
warmed it. According to Galen it inclosed a dry heat; and
he advises persons of a warm temperature not to enter it,
but rather to use the warm bath, where the water absorbed
by the pores would hinder the heat from being attended
by any bad consequences. The laconium also had its name,
as having been originally derived from Laconia. Martial
says to one of his friends (IV. G. ep. 42):

Risus et lubet plantum laconium,
Contentus potes arodeo vapore.

Cruda virgine Martiique mergi.

Dion informs us, that they who perspired in the laconium
anointed themselves with oil, and then entered the cold bath;
nevertheless in its origin the laconium was only used by old
men and valetudinarians. This room, agreeably to Vitruvius,
as well as to the ancient paintings of the baths of Titus,
joined the tepidarium, and communicated to it a more tem-
perate heat. A fort of furnace was usually suspended at the
corner of the room, of a circular form, terminating in a
small spout, open at the top; which, as Vitruvius says, served
to regulate the degree of heat which the bathers would
give the room. It seems beyond a doubt that the laconium
itself was nothing more than a kind of furnace; and the
mists it has occasioned owe their rise to the room in
which it was placed having taken its name from it. In
the paintings of Titus's baths, it is called the concamerata sudatoria;
but Vitruvius furnishes us with a proper distinction, when he
says (I. v. e. 10), "laconicum sudationis locum con-
jugantem tepidarium;" and explains himself more fully in the
next chapter, where he reckons the floors as a chamber of
the palestra. There stood in one of its corners, he says,
was placed the laconicum, and in another the warm bath.
"Concamera sudatoria longitotnique duplex quantram latitudine
qua hebat in veritas ex una parte laconiuni . . . . ex
adverso laconicum calida lavationem." It should perhaps
have been before observed, that according to Vitruvius,
the laconicum had niches which were called sudatories,
where those who used the dry baths seated themselves, as we see
in ancient paintings.

The fifth apartment was the balneum, or warm bath,
called thermolonyx, and was the most referred to. Its size
was proportioned to the number of those who bathed in it
at once. Its breadth was a third less than its height,
without including the gallery, called solabo; which was
carried round it, and terminated near the basin with a little
wall for the bathers to lean against. This gallery was
sufficiently large to contain those who waited for their turns
to bathe. The middle of the room was occupied by a basin
called piscina, or by a bathing place which had the name
of elecurum, as we see in the balneum of ancient paintings.
The bath was placed immediately below the only window
by which the light was admitted, that it might not be
darkened by the shadows of those who were walking in the
gallery.

The sixth room was the elecurium or orituranum. Here
were preserved the oils and perfumes used both in entering
and quitting the bath; and it was so constructed as to receive
a considerable degree of warmth from the hypocaust.
The hypocaust was a fort of subterranean furnace, which
Vitruvius calls fospenta; the bottom forming an inclined
plane, by a gradual descent from the opening where the
wood for heating it was thrown in; by which means
the heat was increased, and the apartments warmed more ex-
peditiously. It extended under the greater part of the rooms
we have mentioned.

Before these rooms particularly destined to the use of the
bath, there were several others intended for the exercises
previously taken. Such were the piperiferarium, the considarium,
the corceca, the fluidum, the ephebeum, and others: all forming
part of the gymnasia; but which were not always append-
dages of the baths, particularly those of private persons.
Private baths, however, differed greatly in construction
from those we have mentioned. Each possessor followed his
own caprice, either in changing the rooms of which they
were composed, or in making the same rooms serve for
different purposes. The description the younger Pinay has
left us of his bath at Laurentium, is a proof of this. In
this building there was neither apodyterium nor tepidarium;
and the arrangements of its other parts was very different
from that of the public baths. You first entered a spacious
frigidarium; where contiguous to the walls, and opposite
to each other, were placed two baths sufficiently extensive to
swim in. Near this chamber was the meatalurn: you
then entered the hypocaust, the praeparatum, and two other
apartments: one but not magnificent: you afterwards came to
an hot bath, from which the sea was discovered; and
farther on was the philerium, exposed to the open air. To
its inside in Tullion, on entering the bath, we first find
a great apodyterium, a spacious and agreeable chamber for
undressing. This conducted to the frigidarium, which was
darkened, and contained a bath of an appropriate size. When
it was not found sufficiently spacious, there was in the
open air a vault, which might be used for the same
purpose. Not far from the frigidarium was a chamber ex-
posed to the sun sufficiently warm, but left to the
frost; this was the tepidarium. This room had three par-
titions, each having a different degree of heat. The two
first were entirely exposed to the sun; and though the last
had not all the heat of the former, it was equally light.
Above the apodyterium was the philerium, or place of
exercise, for different games. Although Piny does not in-
form us how the bathers employed themselves after having
undressed and anointed, it is highly probable they went up to
the philerium and exercised, defended by another
stairs into the vault, and afterwards returned to the
apodyterium; not forgetting in their way to visit the tepida-
rium and frigidarium. The following description, according to the Hippias
of Lucian, gives another idea of the baths of the ancients,
with the various apartments they contained.

"Having passed the great vaulted hall, to which was an easy
access, you entered a spacious hall for the use of the
domesticus who attended their masters. On the left were
the chambers, where they waited the bath retired; which
were the handiwork and most agreeable of all. Further on
was another hall defined for persons of consideration.
After this apartment, on each side were galleries, where the
bathers changed their dressings. The central, which was both
elevated and well-lighted, contained three baths of cold
water, ornamented with Lацион marble; and had like wise
two statues of the same material, the one of Hygeia, and
the other of Ecphrasis. On leaving this part of the baths
by a low vaulted passage, the building became infinitely
warmer, although the heat was far from disagreeable; this
passage led to a light apartment where the oils and essences
were preferred, which on the right hand had a communica-
tion with the palestra; and the door-polls of which were
covered with Phrygian marble. The apartment contiguous
to this, as Lucian informs us, was more beautiful in its de-
corations than any we have mentioned; its very floor
was composed of the marble already spoken of. It was of a size
sufficiently large for the bathers to walk in, and was fur-
nished with seats. After this apartment you entered a part
of gallery heated; of sufficient length to allow the exercises
of the course. It was inclosed with Numidian marble; and
led to a handsome well-lighted apartment, paved with pur-
ple, where were three warm baths. To leave it, it was not
necessary you should go back by the way you entered, but
across a warm chamber where the heat gradually clim nhi.
All the chambers were lighted from the top; and Hippias
showed great judgment, in constructing the apartments which
contained the cold bath fo as to face the north. In regard
to those which required a greater degree of heat, he exposed
them to the south, the south-east, and well."

It appears from this description, that the bath of Hip-
pias had no apodyterium; there were only at each end of
the frigidarium, which contained the three baths of cold
water, tables on which the dressings were placed. The bathers
entered a warm passage which conducted to the unfrigium
whence having anointed themselves they gained the philer-
rium, the largest and handsomest apartment of the whole.
When the excursions were finished they passed into the hot
bath by a gallery where there was sufficient heat to preface
the privation felt excited in the philerium: so that
when the bathers first entered the warm bath, the difference
they found was scarcely perceptible; since the warmth of
the water was nearly the same with that of the body.
After having used the bath, they returned by a shorter way,
and crossed an apartment where the heat diminished in pro-
portion as they approached the frigidarium where their
dwellings had been left.

The following is the description which Vitruvius has left
us of the Hygeia baths. Having described the different
apartments of the gymnasion, he says: "On the right of
the ephebium is built the coryceum, or the room for show-
ing, dressing, &c.; near which should be the caldarium,
where the land for the wrestlers is preferred; and at the
corner of the peristylium, the boutreum, or cold bath. On
the left of the ephebium, the eleothetium, or apartment for
the essences and oils: near which is constructed the frigidari-
um; whence a passage should conduct the bathers to the
propileum near the floor in the corner of the portico.
Adjoining, on one side the frigidarium, is built the vaulted
chamber for perspiration, which is always made twice as
long as wide; and at one of its angles, usually opposite to
the warm bath, the lacoarium."

The disposition of each of the apartments we have men-
tioned varied still more in the thermes of the Romans,
although their plans evince uniformity to a certain extent.
As the Romans had two peristylium in their thermes, it seems
right to conclude they had a double order of baths. Varrus
proves incontrovertibly, that the women bathed in different
apartments from the men for, in speaking of the public
baths of Rome, he says: "Item primum balneum nomen
coryceum introit in urbem: ubi bina effent conjuncta excip-
icia lavandii cum; ubi viri, alterum ubi mulieres
lavarentur." What Maial and St. Cyprian relate of the
baths, where the men and women bathed indiscriminately,
does not confute this passage; since writers attribute those
indecencies to none but women of infamous character:

"Cum te lucernam balneas extirpavit
Admissit inter bullarum machas."

This separation is conspicuous in the baths of Caracalla; a
great part of which was surrounded by a vestibule which
empirized the principal buildings of the thermes. This
part was divided into hirty vaulted halls separated from, but
perfectly resembling each other. One of these yet remains
entire, and sufficiently indicates how the others were di-
vided. It is approached by a small vestibule. The room
in which the bath was placed, was thirty-one feet in length
by fifteen feet three inches wide; the basin was on marble,
with a border of larger stones extending eighteen inches
from the edge of the hot bath. The cavity between the files
was twelve feet wide by fifteen long. It was divided into
three feet in front by seven or eight steps extending the width
of the bath; four above the brink, and three or four went to
the bottom of the basin: and the whole was lighted by a small
opening at the top. A thousand perfous could bathe in
this part of the thermae at once.

When the water flowed into these baths, it seems to have
been only lukewarm, as it was brought from the hot baths
of the great thermae; of which these, as we have already
mentioned, formed only the outer circle. The water was
conveyed from these baths, by pipes, into a great piscina,
or pool, defined for the use of those who wished to exercise themselves in swimming.

In front, on the right and left, were other baths for people of finer connoisseurs. In the room of baths they had three bathing vats, which were of copper, porphyry, granite, or bronze. They also contained large vats of warm and cold water, of which we see a great number at Rome. One may observe, affixed to the baths of Caracalla, had in his time fifteen hundred.

The grand hall was a rotunda, 111 ft diameter, which is believed to have been called cela/Julia, or the hall of fountains, of which Spartanus speaks in these terms: "Cælum Foraminum architecti negatis pulsibus,quit vacuitates qui facta est ita." It seems to have had its name from the bars of copper and bronze which, according to some, formed its pavement, and to others its ceiling; bearing some resemblance to the fountains among the ancient Romans. It had also large plates of bronze or copper, which covered and ornamented the piers of the windows and other parts of the rotunda. It contained a number of vats in which the warm bath was taken.

Of all that relates to the baths, nothing has so embarrassed the learned as the manner in which hot water was heated to all the recesses but for bathing which have been found. For it was imposed, and it may be done without exaggeration, that each bath in the thermae of Diocletian was capable of supplying for bathing the poor perfum might have been put into it. But as no vats remain, insufficient to form even an idea of the manner in which the water passed into the vats, we must content ourselves with what Varro has said upon it. - Baccius has treated this subject better than any of the moderns. He imagines the water was conveyed from reservoirs outside the thermae, and that those were used for raising it to that height, which, agreeably to his examination of Diocletian's baths, seemed requisite. He was also induced to conclude, that the water was heated outside the thermae, from the number of pipes which he saw underneath the area of the building; where there had never been any alteration, and which were all forded by other pipes from the hypocaust. But this supposition appeared to Baccius himself to be ridiculous; that he pushed his researches on this matter no further.

The two figures of the water towers or reservoirs for the baths of Caracalla, engraved by Piranesi, will suffice to explain how easily the Romans heated the largest body of water their thermae could contain.

The water tower of Caracalla received its supply from the aqueduct of Antoninus, part of which passed by the Appian way.

It appears from the plan of this reservoir, that it had, immediately above the hypocaust, twenty-eight vaulted chambers; that these chambers formed two ranges of fourteen each, and that they had a communication one with the other. Above these were twenty-eight other chambers, which were connected with each other in like manner, though only one of them communicated with the chambers below. Above all these was a spacious reservoir, not very deep, but which extended the whole length of the water tower; in this, the water received considerable warmth from the heat of the furnace, before it passed into the chambers. This reservoir did not receive its water directly from the aqueduct, but from an intermediate cistern. Whenever it appeared necessary to draw off the water of the lower chambers to fill the bathing places, the water of the reservoir became uncleans, and would have overflowed but for an opening on one side of the cistern, by which it escaped without going into the baths. During all this time the water of the reservoir was tepid. The cistern suffered two purifications; it prevented any agitation in the water of the reservoir, and carried off that which was of no use. When the twenty-eight vaulted chambers, in medially above the hypocaust, began to heat, the warmth they acquired was quickly augmented; as there was only one of them which communicated with the exterior air.

The strength of the walls and vault was quite sufficient to resist the rarefaction of air within the water, and to confine the water not to hinder its evaporation from producing danger. It was necessary that it should have pipes to give the water a sufficient heat for the usage of the bath. When the hour of bathing came, the warm water was let into the bathing places from the lower chambers; where it ran with incredible swiftness, and rose to a perpendicular height equal to the surface of the reservoir of the water tower.

To hinder the water from cooling as it passed through the subterranean pipes, they were enclosed in others which came from the entrance of the hypocaust, forming a sort of double tunnel, and acquiring a considerable degree of heat before the water entered them.

Each chamber was within the walls 49 ft long, 27 wide, and about 30 high. The number of square feet on the surface of the lower chamber amounted to 8,350. If we allow for the medium height 30 feet, the quantity of water contained in the lower chambers amounted to 1,143,450 cubic feet.

The ancients do not inform us how they discovered the method of heating such large volumes of water. We are therefore in the dark whether it was an invention of the Romans, or whether they brought it with them from the East. It is reasonable, however, to suppose, that such methods could be of no use before the construction of the thermae at Rome, and of course could not be older than the time of Augustus; in whose reign, Dion Cassius informs us, Maecenas built a warm bath capable of admitting persons to swim in.

This method, or one very similar, was used in all the baths of Rome. That of Terme by Vitrivius was insufficient to furnish water for these vast buildings, which Anniusius Marcellinus compares to provinces (lavacra in modum provinciarum extra) ; though it was undoubtedly the caele in private baths. They heated the water of the bath, says Vitrivius, by means of three vats of copper, so disposed that the water flowed from one to the other. One was called caldarium, another tepidarium, and the third frigidarium. The marquis Galani observes, that it is no easy matter to give a precise idea of the situation of these vats above the furnace. Cæsariano and Caporali have engraved one above the other, or rather one within the other, placing the frigidarium above the tepidarium, and that above the caldarium, which was placed immediately above the furnace. But the great difficulty is, that in this arrangement the heat, by the aspiration of the flame, ought to warm the upper vats, or frigidarium. Perrault, on the contrary, places the three vats on a level; and he imagines that syphons carried the water of one vats to another: but how, without a pillow, or some such expedient, the water could be raised so as to re-defend, he has not explained.

The ancient paintings of Titus's baths place these vats upon three steps, in such a manner that the bottom of the water of one vats shall be upon a level with the aperture of the other; so that it is easy to comprehend how the water was conveyed. But the marquis Galani believes, that this disposition is not altogether agreeable to the truth; and that it was adopted by the painter, only to afford a more clear idea how the water was transferred.

I believe,
B A T H.

I believe, he says, that the three vases were upon a kind of level: the caldarium immediately above the furnace; the tepidarium a little back ward, so as to receive a reverberation of the heat more than the fire itself; and the frigidarium upon a muffy pedastal, so that the warmth could not reach it. From the caldarium to the baths was a pipe, which, by means of a cock, supplied any quantity of water that was requisite. Another pipe carried the water of the reservoir to the frigidarium, and kept it at the same level. All the figures which this has given us, have caused me to request that an ancient should overlook this translocation of the water: but that author himself tells us, that the operation was performed without such ease; its collection was not tepidarium in caldarium quantum aque calde extas inert de frigidario in tepidium ad calumnum modum.

They had also other means of heating the water of the baths. We construct, says Seneca, a species of vases high and narrow, in the form of dragons and other fanciful shapes, in which we place pipes of native copper, of a spiral form, through which the water pusses till it acquires a sufficient degree of heat. In the same degree as the cold water enters the pipes, the warm pusses out; so that all the water which runs through, acquires the same temperature. Seneca explains that it was to this purpose, that he has seen in the tunnels through which the water pusses having no communication with the fire, the vapours are not mixed with smoke; nor allow vaporem evaporo, qui certa perturbetur.

The parallel which Seneca has given in his letters between the baths of Scipio Africanus and those of his own time, is highly interesting, and will probably elucidate much that has been already written on the subject.

"Scipio’s bath," he says, "was small and somewhat dark, agreeable to the ancient custom; for our ancestors thought that a bath could not be warm enough unless it was close. It was therefore a great pleasure to me to compare the manners of Scipio with our own. In this little nook did Scipio (the dread of Carthage, and to whom Rome was indebted for having once taken it) use to bathe his body when fatigued with domestic labours. Under this low and forced roof he reposed, and disdained not to tread the vile and mean a floor. But who is there in our time who would condescend to bathe in this way? A man thinks himself poor and mean, unless the walls are decorated with large and precious embellishments; unless Alexandria marble is polished and inlaid with Numidian rough cast; unless a rich and curiously variegated plastering be spread upon them in profusion; unless the roof is covered with glass-work; unless the Thasian stone, once reckoned a scarce and curious ornament, even in home temples, now composes about the pools in which we bathe our bodies when 'enfeebled with fatigue at some thrilling sport.' In short, unless the water is conveyed by a silver front. I am speaking as yet of common baths; but what shall I say when I come to speak of our freemasons? What noble statues! What vast pillars, supporting nothing; but placed there for mere ornament, and the vain ostentation of expense! What large and far flowing extravas! We are arrived to such a pitch of idlecey and extravagance, that we cannot tread but upon the most precious marbles.

In Scipio’s bath there are some chinks, rather than windows, cut out of the stone wall to let in the light without hindering the strength of the building. But now we call the baths moth-houses and dungeons, if they are not so contrived as to admit of those that love the air’s free and spacious widths, whereby men are trained as well as washed; and from the bathing vessels have a prospect both of the meadows and the sea. So that these baths, which, at their first construction, called together a vast concourse of people, and filled them with admiration, are now rejected as poor antiquated things; while luxury is daily presenting some novelty that shall at last prove its own ruin. Formerly there were but few baths, and those not ornamented with any costly decoration; for to what purpose is it to adorn a common room, open to any one that pays his money, and which was built not for pleasure but for use? It was not customary to have the water sprinkled or poured in upon the bathers; nor did it always run freely, as from a warm spring; nor did they think it material, how far the water was whither they were to wash off their bath."

From this letter of Seneca, we perceive to what a pitch of magnificence luxury had carried the edifices defined for the baths. And nothing gives a stronger confirmation to the account, than the fragments of the buildings which have reached our own time. The greater part exhibits to us the most precious furniture. The hall of the bath, discovered a few years since at Otricoli, has preferred the relics of the rarest marbles; its pavement was formed of the same wonderful kind of mosaic which at this day ornaments the rotunda of the Vatican museum. In the baths of Titus, the marble coating is carried to the height of about ten feet, where it is ornamented with small holes, which were designed for the warm baths, had no openings to admit the light; at least none have been found. When it became fashionable to frequent the baths by night, it was necessary the place should be lighted by lamps and candleabra; the introduction of which contributed very much to the decoration of the apartments. The most magnificent we have seen at Rome, have been found in the Thermae: their light was reflected by mosaics of crysfal, suspended from the roof or fixed against the walls, so as to produce the most diffusent light.

The use of glass in the decoration of the baths, commenced about the time of Pliny, who calls it a modern invention: novitium et hoc invenit. It did not exist, as far as has been discovered, in Agrippa’s time; whose baths were covered with ornamented clay or stucco, called albanum opus.

Having thus brought the history of the Roman baths to a conclusion, it will not be irrelevant to add a brief notice of the principal ruins of them which remain, taken chronologically.

The better half of Paulus Aemilius’ baths is nearly perfect.

Those of Livius, on the Palatine hill, and under the ruins of the imperial palace, still shew two small apartments entire, decorated with fresco, painting, and gilding.

The magnificent ruins of the baths of Titus, Caracalla, and Diocletian, still shew the entire plans: sufficient remains of the walls to determine the sections and elevations with tolerable certainty; and of the construction of the courts and aisles, enough to give the most satisfactory information.

There are some remains, but very incomplete, of the baths of Constantine, in the gardens of prince Colonna.

At the rest of the ancient baths, in or about Rome, are newly or entirely discovered; and it is to be remarked, that the baths of Titus, Caracalla, and Diocletian, are entirely stripped of their magnificent columns and fine marbles, excepting the great hall of Domitian’s baths, which was converted into a church by Michael Angelo, and its granite columns of single stones, each forty feet in height, preserved.

That
BATH:

That the Romans, who enjoyed dominion in our island near four hundred years, had these baths, is evident from the frequent mention of them which are found; and some indications occur where the builders had undoubtedly the remains of their parent country in view. At Hovingham in the north Riding of Yorkshire, 1743, a Roman bath was discovered, which had its fudaria and vaporarium (Can. Hill, ed. 1789, ii. 855); and ten years after, in taking down the abbey house at Bath, to build a new set of baths called the duke of Kingston's, the workmen found remains of very noble Roman baths and fudatories, whose forings and drainages were made use of for the present baths. The plan and elevation of them were engraved by Mr. Gough. (Ibid. i. 75.)

Not while mentioning the ancient baths in England, must we forget one instance where a magnificent building of the kind occurs among the monstrous conveniences of the middle ages. Hugh the facet of the monastery of Durey, we are told, early in the twelfth century, finished the aulam hotitum and baireatorium of his house; and Sampson, who was elected abbot in 1182, appears to have completed the latter edifice upon a scale, for those times, peculiarly grand. (Aqueductum et aquam per rinsulos derivatam et lavatoria opere mirifico et magnitudine miranda confunnavit.) See Leland, Itin. vol. iv. App.

But it must be owned, that in spite of all the advantages derived from the habitual use of baths with respect to health and cleanliness, the moderns have till lately very much neglected to employ them; though from this custom we must except the Orientals and the Turks, among whom the practice of the bath has been more early preferred, on account of its connection with religious worship. Their manner of bathing is very similar to that of the ancients; they have still vall edifices for the purpose, which are heated by means of pipes, and receive light from the top: and though the use of the triglia (see Architecture, Plate III.) may not have been preferred, proper frictions for the excitement of perspiration are still used; and the instruments adopted by the ancients are replaced by rough cloths and flannels. The rich among them have private baths, in the construction of which they are expensive, and devote to them the most considerable part of their mansions.

Among the modern Europeans, the practice of bathing, generally speaking, has returned to the fame condition it was in when Homer described it in the earlier ages of Greece. It is in the river, during the heat of summer, that the multitude bathe; and that more for pleasure than on any other account: without once reflecting on the accidents which are likely to result from the crudity of the water, the intemperance of the air, or the action of the sun, to which they are frequently exposed.

At Florence, on the bank of the Arno, public baths were constructed by the late duke, with such accommodations as seemed most appropriate for general use: adjoining which are other baths belonging to private persons; and gardens of promenade.

What are called public baths at Paris, are far from uniting the advantages; they are no other than large boats, called tonne covered with a cloth, with small ladders attached by cords, to facilitate the purposes of bathing. The French have also private baths for hire, similar to those in England; and many of their larger mansions are furnished either with domed baths of the larger kind, or bathing vessels formed of metal.

Those which are called natural baths, are usually buildings constructed nigh the sources of mineral waters; such as the baths of Puzzuoli, Baia, and St. Germano, near Naples; P 69, in Tuscan; Bourbon and Vichi, in France; Duxton, Bath, and Harrowgate, in England.

Of the engravings which accompany this article, Plate I. exhibits the plan of the baths of Caracalla; of the references in which we give the following explanation:

1. The great square, surrounded by a portico, for the exercises of the flumen.
2. Those parts of the porticoes which served for entrance to the ventilates of the palæstra.
3. The cella solaris of the palæstra; the gates of which were furnished with lattice work of bronze.
4. Ventilates of the great hall.
5. The great hall, furnished with the xyllum.
6. Other ventilates belonging to the lateral apartments of the palæstra.
7. Others nearer than those already mentioned, leading to the same apartments.
8. Halls, open at the top, whose sides were ornamented with baso-relievo in marble. A fragment of one of the last of these was lately in the possession of cardinal Albani.
9. Anti rooms belonging to the xyllum.
10. Common entrances to the same.
11. Openings to give the xyllum light.
12. A spacious xyllum in the middle of the palæstra, for the exercise of the athletes.
13. Apartments in which the athletes anointed themselves and left their vestments, with staircases ascending to the upper part of the cella solaris.
14. Reception for the rain-water from the roofs of the porticos (fig. 14.), which was conveyed by pipes to the lower baths.
15. Other uncovered receptacles, for the same purpose, formed in the side walls.
16. The portico, whence passing through the xyllum you reached the great bath: it was exposed to the S. W. and was sometimes warmed by the sun, and at other times by furnaces.
17. Chambers or baths belonging to the wrestlers, and other combatants, of the theatre and xyllum.
18. The cistern of water in the centre.
19. Porticos, ornamented by niches, with magnificent fountains; serving as a shelter for the populace from the rain and sun.
20. Double portico before the theatre.
21. Seats for the spectators at the games; in front of which, upon occasion, the flagge, and scenes for theatrical representation, were erected.
22. Open spaces between the porticos and the great hall or salon.
23. Uncovered hall.
24. The athenaeum.
25. Open space in front of philosophic walks.
26. The philosophic walks.
27. Quarters for the pratorian guard.
28. The great exerci, for trials of strength.
29. Apartments appertaining to the exerci, subdivided into smaller ones for the accommodation of the officers and exterferes in the different games.
30. Apartments for the scenes, and other theatrical apparatus.
31. Openings with iron gratings, for the admission of light to the lower story.
32. Staircases from the lower to the upper story.
33. Ventilates of the upper story.
34. Other staircases of ascent to the porticos.
35. Quarters of the pratorian bands; with porticos in front.
36. Painting,
B A T H.

56. Piazzas, or pools of cold water.
57. Porticos erected at a later period, by Alexander Severus.
58. Cold bath with fountains in the centre.
59. Walks for public accommodation.
60. Magnificent fountains.
61. Walls surrounding the summit of the hill on which the baths of Caracalla were erected.
62. Open space around the referrvoirs of water.
63. The aqueduct of Antoninus, which supplied the baths.
64. Intermediate referrvoir, into which the water of the aqueduct was discharged.
65. The opening by which the water was conducted to the warm bath.
66. The referrvoir.
67. Walls of the city, anterior to those of Aurelian, which were enlarged by Caracalla, for the extention of the thermae.
68. The fountains mentioned in fig. 58.
69. Porta Capena in the city wall.
70. Porta Tarentina.
71. The Appian way.

Plate II. exhibits a painting from the baths of Titus, on a brown ground, representing three flite temples; in the centre one a flate, supposed to be Apollo, with a priest on either side; and above each of the lateral temples a bas-relief, representing the facilities of Bocchus. The smaller figures in Arabifque.

Here may be remarked, that in flift contradiction to all that is affixed by the French writers, the paintings of the ancients, whether Greek or Roman, are in bad perspective.

Plate III. contains a fection of the baths of Caracalla, from Panache; with Montanell's idea of explaining the relative situation of the different apartments in the Roman thermae.

Bath, in Jewish Antiquity, is the name of a liquid measure, containing the tenth part of an acre.

Some dilligently five kinds of baths: viz. the greater bath, containing 80 pounds of water; or, according to Josephus, 1440 Roman ounces; the second, containing 120 ounces; the third, 60 ounces; the fourth, containing 25 ounces; and the fifth 6½ ounces of water. Beveryn. Sync. de Metf. p. ii. p. 127.

Some have esteimmated the sacred bath at half as much again as the common bath; but there is no fufficient reason for this dihcufion. Cabinet.

Ba'th, Knights of the. This order was instituted in England at the coronation of Henry IV. in 1399, and revived by Geo. I. by his letters patent. bearing date at Wellmiflcr, the 18th of May in the 11th year of his reign, 1725, in the following words: "George, by the grace of God, of Great Britain, France, and Ireland, king, defender of the faith, &c., to all to whom these presents shall come greeting. Whereas our royal predecessors, upon divers wise and honourable considerations, have, on occasion of certain royal solemnities, conferred with great latitude, upon their royal issue male, the princes of the blood royal, several of their nobility, principal officers, and other persons distinguished by their birth, quality, and personal merit, that degree of knighthood which hath been denominated the knighthood of the bath; we, being moved by the fame considerations, do hereby declare our royal intention not only to re-establish and support the said honour of knighthood in its former luster and dignity, but to erect the same into a regular military order; and, accordingly, of our especial grace, certain knowledge, and mere motion, and by virtue of our royal prerogative, being the fountain of honour, we have instituted, erected, constituted, and created, and by these our letters patent, do institute, erect, constitute, and create a military order of knighthood, to be and be called for ever hereafter by the name and title of "The Order of the Bath," whereby we, our heirs and successors, kings of this realm, for ever shall beoverege; which said order shall consist of a great matter, to continue during the pleasure of us, our heirs or successors, and thirty-six companions, to be from time to time nominated and appointed by us, our heirs and successors, wherein a Señor shall be always regularly continued; which said order shall be governed by statutes and ordinances, to be from time to time made, ordained, altered and abrogated, by us, our heirs and successors, at our and their pleasure. And to the end that such statutes may be legally established, we, following the example of our royal predecessor, king Edward the Third, of glorious memory, founder of the most noble order of the garter, who gave function to the statutes of that order, by affixing to them the seal which had been by his command made and appointed for the same order; do hereby declare and appoint, that a seal shall be immediately engraven, having upon one side the representation of our royal person on horseback in armour, the shield azure, three imperial crowns, or the arms usually ascribed to the renowned king Arthur, with this circumfcription, "Sigillum Honoris Insignis Ordinis Militaris de Balene;" and on the reverse, the same arms emblazoning our royal arms and our royal will and pleasure, that the said seal shall for ever hereafter be the seal of the said order of the bath; and that the statutes to be perpetually and inviolably observed within the said order, shall be established and sealed by and with the same seal: and we do hereby for us, our heirs and successors, declare and ordain, that the said statutes to be given by us, our heirs or successors, to which the said seal shall be affixed, shall be of the same force and validity as if the same statutes, and every article of them, had been webstholm recited in these our letters patents, and had been passed under the great seal of this our realm. And further, we do hereby ordain, constitute, nominate, and appoint our right true and right entirely beloved confab John duke of Montagu to be the first great master of the said order, to hold the said office during our pleasure, with such powers, privileges, and emoluments, and subject to such regulations as shall be for that purpose appointed in the statutes to be established by us, our heirs or successors, aforesaid. And whereas it is absolutely necessary, for the dignity and service of this order, that there should be officers peculiarly appropriated thereunto, we do by these presents, for us, our heirs and successors, will and ordain, that there shall be for ever hereafter a dean, genealogist, king of arms, regifter, secretary, usher, and teller, of and belonging to the said order, whose respective duties, privileges, emoluments, and perquisites shall be particularly expressed and declared in the said statutes; and we do hereby for us, our heirs and successors, constitute, create, and appoint the dean of the collegiate church of St. Peter's Wellmarsh, for the time being, to be for ever hereafter dean of the said order, and do for us, our heirs and successors, give and grant full power and authority to the great master of the said order, for the time being, to constitute, nominate, and appoint, under the said seal hereby appointed for the said order, a genealogist, king of arms, regifter, secretary, usher, and teller of the said order; and from time to time to fill up the places of such officers upon vacancies, according to such rules and directions, as shall for that purpose be laid down and expressed in the said statutes to be given as aforesaid. And to the end that the respective
BATH.

Respective fees to be paid to the several officers of the said order of the bath by such persons as shall be nominated unto and accept the honour of a companion of the said order, may be certain and fixed, we do, by these presents, for us, our heirs and successors, will and be erect that all such fees shall hereafter be allowed and assessed according to the usual and long-established usages in such matters, and to be sworn and ordained and to be paid on or before the first day of May in every year. After the investiture, the knight wears on his breast and on the left shoulder the four-angled and enameled gold badge, which shall be placed over his heart, the one yard in length, and one yard three quarters in breadth, fringed about with red and white silk; and that, in the lowest margin, the name and title of the knight shall be inscribed with letters of gold upon a black ground; and that the crown, helmet, and sword shall likewise be affixed to the said badge, together with an escutcheon of his arms and supporters, enamelled within a circle gules, having thereon the motto of the order in letters of gold, and his name and title in like manner as the knights of the garter are in St. George's chapel, Windsor; the arms also of his three esquires are enamelled on one plate, with their names and title affixed thereto, and placed under the knight. At an installation of the order, each knight is allowed three esquires, who must be by the statutes "gentlemen of blood, bearing coat armour": they precede their knight in the procession, having for their device a crimson flag with the letters of the knight's name, and the motto of the knight's garter, and twelve thrones, the whole of which are of crimson, with a furcast of white silk set with gold buttons, having a hood of the same affixed thereto, and on the right shoulder of the furcast the plate of cut out of the order, "azure, three imperial crowns". A black silk hat or coat: for which each esquire shall, during the term of his life, enjoy all rights, liberties, privileges, exemptions, and advantages which he enjoys by the presence of the sovereign's body, or the gentlemen of the procession, and which is granted to esquires, or are entitled unto by virtue of any grant, prescription, creation whatsoever; and the eldest of every of those esquires shall have the addition and title of esquire in all acts, proceedings, and pleadings, provided that all those esquires to be entitled to these privileges, shall have certificates of their qualifications before their respective admission, and likewise an exemplification of their actual performing the duties of the creation of any knight or knights of the bath, attested by the great master under the seal of the order. An esquire of the order is allowed to hunt and fish in the king's liberty, and is exempt not only from serving the office of a high sheriff, but any private office. To prevent any abuses in the chasing these privileges and exemptions, the following notice was inserted in the gazette, previous to the installation of the order in 1805, when twenty-two knights were installed, attended by their esquires. Every esquire, therefore in this order, is hereby advised, that no exemplification will be made to any esquire from his royal highness the duke of York, after the enacting of the following resolution, that it shall be certified to his royal highness by the generalissimo, that the degree and coat armour of the several knights and their respective esquires have been entered in the genealogical books of the order, in obdience to the said statutes.

Given at the Hoftie guards, this 13th day of May 1803; Frederick, acting as great master of the said most honourable military order of the bath.

The dries of the officers of the order is as follows: viz. the marshal and esquire of the deann are the same as the knights; he wears a gold chain, with the badge of the order, but no collar. The generalissimo, king of arms, regent, secretary, and others is a white mantle mantle or robe lined with crimson, having
having on the right shoulder the badge of the order tied about the neck with a cord; the same as the knight’s; under it is a fur coat like the esquire’s, with a gold chain about their necks, to which is pendant an effuetece of gold thereon enameled the badge of the order; except that on collar days, the badge is worn pendant to a red ribbon. The office of genels-affair is a distinct office of record for the pedigrees and coat armour of the knights of the order and their esquires, which are entered in a regular series from the year 1359 to the present time. The office of genels-affair has, from the revival, been successively filled by John Anlisi, esq., John Sibbald, Dr. Wynn, esq., and George Naylor, esq., York herald, its present full flour.

The order of the bath doth not appear to have been of greater antiquity in this kingdom, than the reign of Henry IV. who, on the day of his coronation, conferred that dignity upon forty ex esquires, who had watched all night before, and had bathed themselves; yet this degree of knighthood may justly boast of a much earlier antiquity. The learned William Canvon, and Jean du Thiet suppose it to have been practised by the old Franks, or inhabitants of Lower Germany; with whom Mr. Anlisi (who was genels-affair of the order on its revival) is of opinion, the Saxons, who invaded England, had the fame common decent; and who, upon their settlement in England, introduced the same method of knighthood. Dr. Thiet further remarks, that those ancient Franks, when they conferred knighthood, observed many solemn rites. Before they performed vigils, they bathed, to signify that such as were admitted to this degree should be of a pure mind and honest intentions; be willing to conflict with any dangers or difficulties in the cause of virtue; take care, both in their words and actions, to follow the maxims of prudent; and, on all occasions, religiously observe the motto of the order. “Tria juncta in uno!” which implied a true belief of the Trinity: which rites and conditions, according to his testimony, still continued to be practised in England; and from the practice of these, gentlemen were denominated knights of the bath. Mr. Anlisi, with his usual precision and clearness, hath fully proved that William the Conqueror, and the succeeding kings of England, conferred this degree of knighthood as well in Normandy as in England. We have a very particular detail of the ceremonies that were used in creating knights of the bath at the coronation of King Henry V.; and our historians and records imply much that from that time till the reign of King Charles II. inclusive, it was the usual practice to create knights of the bath at, or previous to, the coronation of our kings, the creation of princes of Wales, and at the celebration of their nuptials, and those of others of the royal family. King Charles II. previous to his coronation, created no less than sixty-eight knights of the bath; from which time no knighthood of that degree were created, until the revival by George I. in 1725.

Bath metal is a preparation of copper with zinc, which gives a more beautiful colour than the calamine used in the preparation of the common brass.

Bath Kol, in Jewish Antiquity, a species of revelation by a voice or echo from heaven.

The word signifies, in the Hebrew original, daughter voice, or daughter of a voice; for it may be interpreted both ways. It seems to have been thus called with respect to the original voice delivered from the mercy-seat, when God was confounded by urim and thummim; this latter was the grand and primary voice of revelation; the former of secondary dignity, and inferior to it as the daughter to the mother.

The Jewish writers speak of three kinds of revelation among them; the first by urim and thummim, which obtained from the erection of the tabernacle to the building of the temple; the second by the spirit of prophecy, which prevailed from the beginning of the world to that of Masachi; the third, the bath kol, or daughter voice, which took place when the spirit of prophecy wholly ceased in Israel; and was, says Grotius, the sole oracle which remained during the time of the second temple.

This bath kol, says Dr. Prideaux, was no such voice from heaven, as the Jews, and particularly the Talmudists, pretend; but only a Scharshalk mode of division of their own invention, resembling the “Sors Virgines” among the heathens. (See Everts.) Phil. Comm. pt. 2. b. 5. vol. 1. p. 465. Grotius, Works, and Aaron, lib. 4. c. 6. Lychotz’s Works, tom. 1. p. 485. Grot in John, xii. 28.

Bath has a different on the purity and impudence of the bath kol: “De filia vocem, etc. dixit Iovis, annum nulma.”

Bath, in Ancient Geography, the ruins of an ancient city of Africa, in the kingdom of Algiers, about two leagues south of Oran, which was destroyed in the wars that raged between the African powers, about the beginning of the seventh century, it has been remarkable, in more modern times, for a little chapel, erected in memory of a merchant, who lived among these ruins, and by the presents he received for his hospitality to travellers, became rich enough to maintain 300 disciples, whose employment it was to go through a long litany of all the divine attributes, by the help of their beads at certain hours of the day; but the feat has of late declined and is almost extinct.

Batha, a town of Ethiopia, near Egypt. Pliny.

Batha, Bach, or Bashia, in Geography, a town of Hungary, situate near the Danube, and capital of a county of the same name. It was formerly the see of a bishop, now united to Colocza; 20 leagues south of Buda. N. lat. 40° 40’. E. long. 20° 40’.

Batha, a town of Ethiopia, on the confines of the country called by the Arabs Barbera, and more commonly Zanguebar.

Batha, a name sometimes given to the isle of Bath, which see.

Bathasca, a town of Lower Hungary, in the county of Totha, on the Sarwitz.

Bathenas, in Ancient Geography, a town of Syria, between Cyrus and Edefi. Anton. Ibn.

Bathgate, or Bathget, in Geography, a market town in the county of Linlithgow, in Scotland. There are three fairs held annually in Bathget: second Wednesday in April, first Wednesday after White Tuesday, O.S. fourth Wednesday in June, third Wednesday in July, third Wednesday in August, N.S. and first Wednesday after Martinmas. The circumjacent country is rather chilly, yet by no means defective of agricultural improvement; the soil of late is made to yield abundant crops; and rural economy advances daily. In a mora, about a quarter of a mile from Bathget, some flight traces of the principal residence of Waller, higheward of Scotland, (the founder of the royal house of Stuart,) are still discernible. The mansion, and lands thereto belonging, were the dowry beffowed on the higheward’s wife, lady Margery, by her father, king Robert the Bruce. in A.D. 1316.

Bathing, the act of using or applying a bath; that is, of immersing the body, or part of it, in water, or other fluid. See Bath.

Bathing, on a religious account, is more properly called ablution, or baptism.

Bathing is a practice of antiquity. The Greeks, as early as the heroic age, are said to have bathed themselves in the
We even find mention in Homer of hot baths in the Trojan times; but these seem to have been very rare, and only used on extraordinary occasions. Athenæus speaks of hot baths as unusual even in his age. In reality, public baths appear to have been discouraged, and even prohibited, by the ancient Greeks, who were contented to wash themselves at home in a fort of bathing tubs. Pott. Archæol. tom. i. lib. iv. c. 19. The method of bathing among the ancient Greeks, was by heating water in a large vessel with three feet, and then pouring it on the head and shoulders of the person seated in a tub for that purpose. who, at coming out, was anointed with oil. Durett, in Hist. Acad. Infér. t. m. p. 117.

The Romans were also long before they came into the use of baths; the very name of which, thermae, shows they borrowed it from the Greeks. As the ancient Romans were chiefly employed in agriculture, their custom was, every evening, after work, to wash their arms and legs, that they might sit down to dinner with more decency; for it is to be observed, the use of linen was then unknown, and the people of that age went with their arms and legs bare, and consequently exposed to dust and filth. But this was not all; for every ninth day, when they repaired to the city, either to the forum, or to attend at the assemblies of the people, they bathed all over in the Tyber, or some other river which happened to be near, and to them. This seems to have been all the bathing known till the time of Pompey, when the custom began of bathing every day. Mercurial, de Art. Gynm. lib. 1. c. 10. Men. Acad. Insér. tom. ii. p. 114.

The Celtic nation were not without the use of bathing; the ancient Germans bathed every day; in winter in steam, and in summer in cold water. This is what Tacitus seems to forget, "Ritum e formo—lavantur, lupus cultus, aut equal quos pluries hieus occupat." De Mor. Ger. cap. 32.

Bathing, among the ancients, made a part of diet, and was used as familiarly as eating, or sleep; and cold bathing was in high esteem among their physicians for the cure of diseases; as appears from Strabo, Pline, Hippocrates, and Oribasius; whence occur frequent exhortations to walking in the sea, and plunging into cold water. The first influence of cold bathing, as a medicine, is Melampus’s bathing the daughter of the king of Arcos, and the first influence of warm bathing is the use of it by Medea, who was said to boil people alive, because Pelas king of the Thesylus died in a warm bath under her hands. The cold bath was successfully used by Antonius Mafa, for the recovery of Augustus; but after the death of Marcellus, who was thought to have fallen a sacrifice to the improper use of it, the practice sank into neglect. It was again revived towards the close of the reign of Nito, by a physician of Marcellus named Charmis; but it was afterward disused during the ignorance of the succeeding ages. Among the Turks, bathing forms a part of diet and luxury, and in every town and even village there is a public bath for those who have not the convenience of private baths attached to their own houses. Baron de Tott (Mém. de l'Acad.) gives us the following account of the construction of the private baths. Two small chambers, built with brick and faced with marble or gilding, communicate with each other, and each of them is heightened by a small cupola cut in the center. This little edifice is commonly joined to the house by a small room, in which those who bathe undressed, and from doors, folding over and lifted with felt, that in the front and found part of the floor. A wood fire is kept in a little round vault, the entrance into which is from the back of the room. This fireplace is under the farthest chamber, and heated a candle immediately beneath the marble floor, which serves as a ceiling to the vault. Pipes, placed within the walls, proceed from the middle of the caldron, and go out at the cupola, for the purpose of evaporating the water, which is kept continually boiling. Other tubes, communicating with a reservoir, are likewise contained within the brick-work, and turn the inside with cold water, by means of cocks placed at the sides of these which yield the warm water. Small seats of smooth wood are made to sit on, and drains cut in the marble to carry off the water which is thrown down. These private baths, always heated twenty-four hours before they are used, by being then exhausted, provide such a degree of heat, that persons who undressed in a small exterior chamber, and put on high fences of wood to preserve the feet from being burnt by the marble floor, cannot enter the first room with safety till they have stopped a moment between the two doors to let the lungs dilate; after which they cannot enter the second floor, under which the heat is most active, without similar precaution. A sudden perspiration rising through all the pores, is felt immediately as they are entered; but the violence of this heat does not prevent the women from staying in these baths five or six hours, and returning to them very frequently. The following description of the public bath, and the method of using it, is abridged from the account given of the baths at Caro, by Savary, Travels, vol. i. p. 146, &c. The first apartment, or undressing chamber, is lofty and spacious, and, which lies on the ground, is open at the top for admitting a free circulation of the air. A fracasule or raifed floor, covered with a carpet, and divided into compartments, goes round it, on which the persons who bathe lay their clothes. In the middle of the building, a jet d'eau springs up from a bathon, and agreeably entwines the eye. When you are undressed, you tie a napkin round your loins, put on a pair of sandals, and then enter a narrow passage, where you begin to feel the heat. The door being shut, at the distance of twenty paces, you open a second door, and proceed along a passage, which forms a right angle with the former; here the heat increases. Those who are afraid of suddenly exposing themselves to a stronger degree of it, step in a marble hall, in the way to the bath, properly so called. The bath itself is a spacious and vaulted apartment, paved and lined with marble, round which are four closets. The vapour ascends rising from a fountain and cistern of hot water, mixes itself with the burning perfumes, which perfumes are diffused by the porsus who bathe. The bathers extended on a cloth that is spread out, and put in hot water, by a small cushion, stretch themselves freely in every posture, whilst they are enveloped by a cloud of odorous vapours, which penetrate into all their pores. After remaining there for some time, till gentle moisture is perceived over the whole body, a servant press's you gently, turns you over, and when the limbs are become supple and flexible, he makes all the joints crack without any difficulty. He mosses, i.e. delicately touches, and seems to knead the flesh, without making you feel the smallest pain. When this operation is finished, he puts on a glove covered with a piece of coarse fluff, and rubs you for a long time; and during this operation, he detaches from the body, running with a foot or feet of small scales, and removes even the imperceptible filth, that keeps the pores. The skin becomes soft and smooth like fatin. He then conducts you into a closet, pours a lather of perfumed soap upon your head and then withdraws. The closet is furnished with a cistern and two cocks, one for colds and the other for hot water. After having washed in this apartment, the servant brings a deploratory pomatum, composed of a mineral called "rutilum," which is of a deep brown, and which the Egyptians burn lightly, mixed with water, and mix with half the quantity

bathing
quantity of dressed lime. This greyish polce, applied to the
hair, makes it fall off in a little time; and it is generally used
both by men and women in Egypt. After being well waffled
and purified, you are wounded up in hot linin, and conducted
through the walkings that lead to the outer apartment: and
by this gradual transition from heat to cold, or by fropoing
for some time in the baln next the fivo, no inconvenience
arises from the use of the bath. On arriving at the ertrala,
you find a bed prepared for you, and as foon as you are laid
down, a child preffes every part of your body with its delicate
fingers in order to dry you thoroughly. Here you change
linen a second time, and the child-girt gives the coldliny
of your feet with pumice done. He then brings you a pipe
and Mocha cofl.

By their baths, the Savages, the ufe of which the ancients
strongly recommended, and which are still the delight of the
Egyptians, they prevent or depofe inflations, catarrhs, and
such cutaneous disorders as are produced by want of perpira-
tion. Thus the blood is made to circulate with freedom, the
whole body acquires a suppleness and lightness, and the
spirits gain a vivacity and flow, which are not experienced in
an equal degree, by thole who do not pay so much attention to
external coolant. The women are particularly fond of
these baths, and frequent them at leat once a week. After
undergoing the usual preparations, they wash their bodies,
and more especially their heads, with rose water. Here the
female head dresses are formed with hair black hair into trefis,
to which they apply colly infences, instead of powder and
pomadon: They here blacken the auds of their eyelds, and
lengthen their eye-brows with "cannel," or a preparation of
the burn with gall-nuts. Here also they trim their finger
and toe nails with "cone," (See ALCANDA), which gives them a
golden colour. The linen and clothing which they use are
poled through the sweet cream of the wood of aloes. The
lady, appropriated to the ufe of the bath, are fenced
for the Egyptian women, and on this occasion they pay
great attention to the ornaments of their dress, as well as to
the cleanliness of their persons.

Baths similar to that above described, though differing in
fize, are constructed in all the principal towns of Egypt.
The neceffity of coolant in the fomner climates, where perpira-
tion is to cypious, has rendered this bath indispensa-ble:
the comfort they produce, preffures the ufe of them: and
Mahomet, who knew their utility, has refenrenced the
practife of ablation and bathing by express precept.

Mr. TOLLOE (View of the Russian Empire, vol. ii. p. 7, &c.)
forms us, that the common Russians, in general, use but
fome medicines; supplying their place, in all cafes by the
fweating bath, a practice universal among them, and which
has a decided influence on the whole phifical state of the
people. The ufe of the bath, that viecaiie refet of the
manners of the ancient world, as this ingenious writer de-
nominates it, is now almost entirely con fined to the Oriental
nations, where it ministers both to health and to luxury, and
is perpetuated by religion. In Europe it has been gradually
decaying for feveral centuries, though it was here also in
fome fhort interwoven with religion, the holy water of the
Roman catholic church being a flight remnant of it.

Rufia and Hungary are at present the only countries in
this quarter of the world, where it is still the custom to
bathe after the manner of the ancients. In Rulfia, particu-
larly, the bath forms a fubftantir part of the fystem of life,
that it is used by people of every age, and in all circumftan-
ces, by infants, by lying-in women, in almost all ficknesses,
before and after a journey, after hard work, &c. The bath is
a nefercy of life fo indispensable to the common people, that
they frequent it as often as possible, well or ill, and without
any particular occasion, once a week at leat. Perfons of
middle ftation in good circumstances, and the great, infuf-
fly construct vapour baths, after the Rulfian fashion, in their
own houses, though in these classes the practices is not fub-
infeited under the increafing influence of foreign manners. Baths have
been common in Rulfia from time immemorial. They are de-
ferbed by Mofes fowing ago as the 11th century, pricifely
in their present form. Among the ancients the baths were
public buildings under the immediate cognizance of the
government. The invention of them was owing to coolant-
ifs and convenience; but in proof of time all the graces of
architecture were fcribed upon them; and at length luxury
and voluptuousnefs fo pufioedit them from their prifine
purpofes that they became offenfive and shocking to the
moralists of antiquity. All wonder was allowed at the mag-
nificent of the baths in Perif. At Rome, under the em-
perors, there were once 870 of these edifices, such, with
respect to magnificent and table, as might put for make-
pieces of art; and in after ages they were demolifh by the
Goths, or converted by fiphos into ahrches. In our days,
however, Hungary is the only country that can fiil exhibit
baths equal in magnificent to those of the ancient Romans.
In Ruffia, on the contrary, they are always of that fimple
conftuction, which indicates their primitive and molt elfential
destination. Here the public baths, called public becaufe
they are under the care of the police, and let out to com-
mon people on the crown's account, ufually enclosed of mean
wooden boards, laths, where it is pojible, by the aide
of a running stream. In the bathing room is a large vaulted
oven, which, when heated, makes the pavin fones lying
upon it red hot, and adjoining to the oven is a kettle
fixed in molfinry, for the purpose of heating boiling water. Round
about the walls are three or four rows of benches, one
above another, like the seats of a fcafl fiil. The room has
little light, but here and there are aparatus for letting the
vapour escape; the cold water that is wanted being let in
by small channels. Some baths have an anti-chamber for
dressing and undressing; but in most of them this is done in
the open court-yard, which on that account has a boarded
face, and is provided with benches or plalls. In tafe of
parts of the country where wood is scarce, they sometimes
confilt of wretched caverns, confined, dug in the earth
chief to the bank of some river. In the houses of wealthy indi-
viduals, and in the places of the great, they are conftituted
in the fame manner, but with fab, frics, ochtes and conveni-
cence. The heat in the bath room is usually from 32° to 40°
of Rankin; and this is much increafed by throwing over
every five minutes on the glowing hot flakes in the chamber
of the oven. Thus the heat of a s.f-e, confined on the
uppermost bench, to 44° of the thermometer. The perfons
that bathe lie quite naked, on one of the benches where
they perspire more or lefs in proportion to the heat of the
humid atmoilphere in which they are enveloped. Promot-
ing perpirition, and more completely opening the pores, they
are full rubbed, and then gently fpackled with lefty bunches
of birch. After remaining for some time in this flate, they
come down from the sweating bench, and wash their bodies
with warm or cold water, and at latr plungc over head in a
large tub of water.

Many perfons throw themselves immediately from the
bath-room into the adjoining river, or roll themselves in the
fnow to a bals of ten or more degrees.

The Ruffian baths are, therefore "sweating baths,"
not the Roman tepidaria or caldaria of a moderate warmth,
but very violent sweating baths, which to a perfon unbati-
ated to the prattle, bring on a real, though a genic and
almoft voluptuous swoon. They are "vapour-baths," not
water
water nor yet dry sweats or baths; differing in this respect from all the baths of antiquity, as well as from those of the modern Orientals; and in this consists their essential excellence, that they are beneficial in such a variety of cases, where hot-water baths would be usefo or even pernicious. They are further "salutary baths," as they promote cleanliness, assist the perspiration, render the skin soft and smooth, &c. and not voluptuous baths like those of the Greeks and Romans. All the inventions of luxury and cegacy are entirely obviated; and the history after the use of the bath, indispensable in those, the Russian is wholly ignorant. Instead of this the sudden transition from heat to a rigorous cold hardens his body, and adapts it to all the severities of climate, and to every variety of weather, a tradition of which gives to us unshaken or dangerous, merely from the prejudices of a fast and effeminate age.

Mr. Tooke adds, that without doubt, the Russians owe their longevity, their robust state of health, their little distilution to certain moral duties, and their happy and cheerful temper, mostly to these baths, though climate, altitude, and habits of living likewise contribute there share.

The great lord chance for Bacon, and other sagacious observers of nature, and of mankind, have hitherto, and certainly not without cause, that the practice of bathing has fallen into disuse among the modern nations of Europe, and anxiously wish that it might again revive in all our towns and villages. In fact, when we consider, says Mr. Tooke, that the old physicians so early introduced into their practice this remedy of nature's own invention, and employed it with such great success; when we recollect that Rome for 500 years had no physicians but only baths; and that to this day a multitude of nations cure almost all their maladies merely by baths; we cannot avoid regarding the dismission of them as the epocha of a grand revolution, which has been wrought in the physical state of the human race, in one quarter of the world. The natural perspiration, the most important of all exertions, must naturally go on better in a body contantly kept soft by bathing. Many impiuries that privily lay in us the train to cedions and dangerous distempers are removed in time, before they poison the blood and juices. All exanthematic diseases are abated by bathing, and consequentiy the small pox; and if this dreadful disorder he actually less fatal in Ruflia than in other countries, this pheenomenon need not be attributed to any other cause besides vapor or baths.

Bathing, medicinally confidered, ranks among the most efficacious means by which diseases are prevented or cured. Its effects vary according to the variation of temperature, and according to the qualities of the liquid medium employed; that is, according as the bath consists either of common water, or of water containing salt or other mineral ingredients (see Mineral Waters), or of water impregnated with the virtues of aromatic or other herbs. These last, which go under the name of medicated baths, are much used; and when they are we are inclined to believe that it is to the watery medium, rather than to such impregnations, that their beneficial operation is to be ascribed.

Under the present head, we shall confine ourselves to the consideration of the effects produced by bathing, so far as they depend upon a diminution or increase of temperature above or below the natural bandom of the human body. Bathers of different degrees of temperature, corresponding to the familiar terms, cold, temperate, and hot, are suited to different and opposite states of the body. The manner of using them is also different; the time of immersion or laying in them varying according to the difference of temperature, and according to the required quantum of impression or effect, as will be particularly noticed in treating of each.

And, last of the Cold Bath, by which is understood water of a temperature from 05 to 33 of Fahrenheit. The general effects produced in a healthy person by immersion into an ordinary cold bath (that is, water of the temperature of 48 or 50) are, according to the accurate statement of Dr. Saunders, as follow: 'First, there is a general sensation of cold, forming that sudden shock to the whole system which is one of the most important effects of the cold bath. This is almost immediately succeeded by an equally universal flush of warmth, which increases rapidly to a certain point, so as to cause the surrounding water, though relatively cold, to feel of a comfortable warmth; and this feeling is sooner produced, and continues longer, in proportion as the person is in full health, and naturally possesses a vigorous circulation. By degrees, however, if the body continues immersed, it becomes chilled; violent shivering comes on; the extremities grow numb and pale; sometimes sickness takes place; and, at last, the animal powers are exhausted by cold and fatigue. In this proceeds the most remarkable effects are those which occur first, and are directly consequent to the shock of immersion; and these require particular attention in a medical view, as it is only in the production of these that the cold bathing should be fulfilled to proceed. The sensations of returning warmth which take place directly after the cold of the bath, constitute what has been called the reaction of the system; and this is certainly a proper and characteristic term, as it imports an action produced in the body itself, to refit an external impulsion. Reaction in this place seems to be a peculiar effort of the living power, and to be excited in a degree proportionate to the force of that power, and to the intensity of the caufe which called it into action. It implies not merely an increase of the production of animal heat, but, superadded to this, a sudden effort within the body, and the whole arterial system, to overcome an impulsion on the extremities as fulminating and powerful. Hence it is that a mere abstraction of heat, by a cold medium will not produce that which is precisely meant by reaction, except the external cold be applied suddenly, and to a large surface. These two conditions are fulfilled by sudden immersion into cold water. The superior power of conducting heat which water poifes over air, is also a circumstance that is always to be kept in mind in applying cold externally. This is particularly thon when a person continues long in this cold medium beyond the first effects of reaction. On account of the high conductive power of water, the body must be constantly employed in producing an unusual quantity of heat; and this appears to be a great effect in the constitution, which, if carried too far, goes directly to destroy the animal powers.' Thus three effects are produced by immersion in cold water; viz., an inflammatoneus and powerful shock, a sudden abstraction of heat from the surface of the body, and that excretion of the vital energies to counteract the shock and restore the lost quantity of animal heat, which is termed reaction. It is easy to perceive that when the body is placed under such circumstances for a few seconds, a considerable impression must be made, first upon the sentient system, i.e., the brain, and its ramifications, the nerves; and, secondly, upon the sanguineous and absorbent systems; and that such impression may be rendered subterfuent to the prevention and cure of various diseases. Accordingly, the cold bath is a principal remedy, first in many conjunctive affections, and in maulcral attacks; and secondly, in certain forms and conditions of fever.

2. In
Bathing.

1. In the convulsions to which children are so liable, Dr. Currie of Liverpool (whose observations on the subject of cold bathing cannot be too often quoted) has found this application a most useful remedy, whether the convulsions originated in worms, or other causes. In early infancy, however, he remarks, that he has used it with caution, sometimes tempering the water when the weather was cold, and sometimes pouring it upon the patient, rather than immerging the patient in it; making the application of the cold water in this way sudden and transient, so as to secure reaction, and avoiding the remedy entirely in all cases where the vital energy seemed much exhausted. He further remarks, that the chief benefit derived from the cold bath in convulsive diseases, depends on its being used in the paroxysm of convulsion. It not only shortens the duration or abates the violence of the exiting paroxysm, but has a remote good effect in retarding or wholly preventing its return. In that convulsive disorder termed erethes vii. vii., the cold bath, though strongly recommended by most practitioners, has not succeeded with this author; and he candidly acknowledges, that his experience of its effects in epileptic fits is as yet too limited to enable him to form any satisfactory conclusion. The late Dr. Heberden, whose experience in these affections was considerable, had no great opinion of it. Again, tetanus, whether idiopathic or arising from local injury, this remedy has been employed with the most decided good effect, particularly in the tropical climates; and it has proved beneficial in manic and maniacal paroxysms. See Dr. Currie's work hereafter quoted.

2. In certain forms and conditions of fever. In these cases, cold bathing, whether by immersion or affusion, is of eminent service when properly applied; as, by abstracting the preternatural degree of heat, it flies the body of an exhausting fluxus and irritation, and thereby abates the frequency of the pulse, the delirium, and other febrile symptoms. It may be referred to in most fevers, (some of the exanthematic fevers excepted) where the skin is hot and dry; but it is especially adapted to the typhus, or common contagious fever of this country, the acutest fevers of the hot climates, and the yellow fever of the West Indies, &c. The safest and most advantageous time (says Dr. Currie) for using the affusion or affusion of cold water, is when the exacerbation is at its height, or immediately after its declination is begun; and this has led me almost always to direct it to be employed from six to nine o'clock in the evening; but it may be safely used at any time of the day, when there is no fever of chilblains present, when the heat of the surface is steadily above what is natural, and when there is no general or profuse perspiration. It is of the utmost importance that medical practitioners be careful not to apply this remedy during the cold fit of fever, when it would extinguish life; nor to apply it when the heat of the body is less than natural, or even only equal to the natural heat; nor when the fever-patient is in a state of perspiration. Cold bathing has also been tried in the febrilina; but in this species of eruptive fever as well as in measles, the application of cold water to the surface of the body is, in our opinion, by no means advisable. Another caution on which we would insist with regard even to fevers that are not eruptive, viz. that when they are complicated (as often happens in this climate) with pneumatic inflammation, cold ablution is inadmissible.

Cold bathing has often been recommended in certain glandular diseases, and particularly in scrofula. Accurate observation, however, has proved, that in these cases it is generally hurtful; and that for such complaints, a temperate bath, whether of fresh or salt water, is preferable.

Having thus described the general effects of cold bathing, as well as its particular application to certain states of disease; we have only further to add a few words respecting the manner of using it. In the case of immersion, the time of staying should in general not exceed a minute or two, where the degree of cold is below 60; but in the summer and autumn fevers, immersion in rivers, and especially in the seas, may be continued as long as is pleasant to the feelings of the patient provided the body is at the same time exercised in exercising. Much mischief, however, is frequently done by staying in too long.

It has been commonly supposed, that if a person has made himself warm with walking, or any other exercise, he must not let him become cooled before he should plunge into the cold water. Dr. Currie, however, has shown that this is an erroneous idea, and that in the earlier stages of exercise, before profuse perspiration has dissipated the heat, and fatigue diminished the living power, nothing is more safe, according to his experience, than the cold bath. This is in true, that he has for some years constantly directed infants to use such a degree of exercise before immersion as may produce some increased action of the voluntary system, with some increase of heat; and thus secure a force of reaction under the shock, which otherwise might not always take place. The popular opinion, that it is safest to go per stictly cool into the water, is founded (he observes) on erroneous notions, and sometimes productive of injurious consequences. Thus, persons heated and beginning to perspire, often think it necessary to wait on the edge of the bath until they are perfectly cooled; and then plunging into the water, feel a sudden chilliness that is alarming and dangerous. In such cases, the injury is generally imputed to going into the water too warm, whereas in truth it arises from going in too cold.

Besides immersion, there are other modes of cold bathing; such as offusion, which consists in suddenly pouring upon the body a sufficient quantity of cold water from buckets or other vessels. This mode of applying cold water produces a very considerable shock, and consequent reaction. It is this mode of cold bathing that has been referred to with advantage in the contagious fevers of this climate, and in the yellow fever of the West Indies. What is termed the flourer-bath is only another mode of effusion.

As cold bathing is a remedy which is successfully employed for the cure of various disorders, so is it a precaution against others, and particularly against febrile infection. When used by persons in health, it increases the tone of the muscular fibres, strengthens the digestive organs, and by diminishing the sensibility of the whole system, and particularly of the skin, renders the body less susceptible of atmospheric impressions from cold, wet, and sudden changes of temperature; thus contributing to the production of what is termed a robust or athletic constitution. A temperate bath (i.e., from 70 ° to 83 °, or more) is applicable to the same cases as the cold bath, and may be used in the same manner. It is preferable in many cases where the shock of the ordinary cold bath is too great.

If after going into the cold bath a person feels dull or chilly, or complains of headache, or tightness across the chest, it is a proof that it disagrees, and it should accordingly be discontinued. It should further be remarked, that this remedy is not suited to those who have a tendency to consumption, nor to such as are constitutionally liable to bowel complaints. The best seasons of the year for cold-bathing are the summer and autumn.

We now proceed to the consideration of Warm Bathing: a remedy not less efficacious than the former in diseases of an opposite nature; but concerning
concerning the operation of which, wrong notions have
till very lately been entertained by the generality
of medical writers and medical practitioners. It has been
imagined that the warm bath relaxes (a figurative
effect) and weakens, whereas it produces a contrary
effect; unless indeed the temperature be so high, or the
time of immersion continued so long, as to bring on that
degree of debility which is accompanied with delirium.
But this arises only from an abuse of hot bathing, and is
even then the consequence of an excess of stimulation. So
far is immersion of the body in water heated to 105 from hav-
ing a lowering or weakening operation, that when duly re-
regulated it is found to reile the spirits, to mend the pulse and
appetite, and to refresh and invigorate the whole frame.
Hence the benefit derived from it after great fatigue; in
old age; in atomic gout, accompanied with swellings and
palpil swellings of the joints; in paralysis; in chlorosis; in
defeases arising from a certain torpor of the lymphatic and
glandular system, such as scrofula, leprous, and other chro-
nic eruptions, &c. In cases of predilection to phthisis, it abates
the frequency of the pulse, and tends to retard at least, if it does not wholly prevent, the pulmonary affec-
tion. In consequence of its soothing and agreeable impression upon
the surface of the body, it produces very beneficial effects in
certain disordered states of the alimentary canal, originat-
ing in diminished action; and it relaxes the bowels and feces
and relief in a great variety of painful disorders, whether con-
ected with local inflammation or not; such as chronic rheumatism, certain forms of dropsy, nephritis, calculous
colics, enteritis, &c.

The time of immersion should be varied according to the
temperature of the water, and the exigencies of the patient.
In a bath of 90°, a person may remain fifteen, twenty,
or thirty minutes, or even longer; but in one of 98 or 100.
it will seldom be proper, and indeed there are few passions that
can bear, to remain beyond ten minutes, and in the gener-
ality of cases not so long. Patients labouring under chronic
rheumatism and palpily bear the high degrees of temper-
ature bath. When sweating is desired (which will seldom happen,
except in cases of local inflammation), the warm bath
should be used in an evening, and the patient should
immediately afterwards be put into a warm bed, and remain
there until late the next morning; but in all other cases,
where sweating is not required, or in which it would be
hurtful, the best time for using the warm bath will be in the
afternoon, about two hours after breakfast. In these cases,
the bathers should not retire to bed, nor confine themselves
within doors, but go about as usual; unless the weather
should be particularly damp or inclement. Hot bathing,
like cold bathing, is applied topically by pumping on the
diseased part, as will be described when we come to treat on
mineral waters. Sometimes steam is applied to the body in-
stead of warm water. See VAPEUR BATH.

Among the works on cold and warm bathing, the follow-
ing are those which seem most entitled to notice: viz.
"Flower on Cold Bathing," 1759. It should be remarked,
however, that this author works without method on this
subject; that he is too indiscriminate in his profiles of the cold
bath, and that he recommends it in some diseases of debility
to which warm bathing is better adapted. "Maced via
Currie's "Medical Reports on the Effects of Water, cold and
warm," 1757. And the 6th chapter of Dr. Sam-

BATHING, a bath or a bade, is, when Inquiry white from
her range feet, and also bird, reimbursed, and ther-
oughly reclaimed, she is offered safe water to bathe her-
self in, a bade, where she may stand up to the thigh,
choosing a temperate clear day for that purpose. By the
use of bathing she gains strength, with a sharp appetite, and
so grows bold.

BATHING, among the Copts and Ethiopians, denotes
the day of Christ's baptism, reputed the 6th of January;
when, from an opinion of an extraordinary faculty in the
waters on that day, they not only, by ancient custom, bap-
tified their catechumen, but were re-baptised themselves.
The water of this day they carry home to keep; and
Cyprian affirms us, that it had been often known to
remain sweet and uncorrupted for two or three years.

BATHING Tab. In the Roman baths there are two kinds
of bathing-tubs; the one fixed, and the other moveable.
Among the latter, some were contrived on purpose to be
suspended in the air; whereby, to the pleasure of bathing
was added that of being swung or rocked by the motion
given to the bathing-tub. Barett, in Hist. Acad. Inscrip-
tom, i. p. 172.

BATHNUS, in Antiquity Geography, a river of Panonia,
near which the young men of the country assembled, laid
down their arms, and threw themselves at the feet of the
victorious Romans.

BATHIS, Bathous, a river of Asia, in the territory of
Celisb, which ran from the east to the west, and discharged
itself into the Euphrates 92,0 leagues south of the mouth of
the Phenus.

BATHIS, in Entomology, a species of Papilio (Pib. run)
that inhabits Sarum. The wings are two-toned, with a
black ocellus spot, beneath brown, suffused with white,
and angle rufous. Fab. 1797.

BATHMONSTER, in Geography, a town of Hungary,
separated by the Danube from Bathem.

BATHOS, in Ancient Geography, a town of the Pelo-
pomnesus, in Arcadia, near the river Alpheus, according to
Pausanias, who adds, that they celebrated every third year
the mysteries of the greater godesses in this place.

BATHRACUS, a port of Africa, in Mararama. Pto-
lemy.

BATHRITITES, the name of a nome of Egypt,
where, according to Luidius, king Vaphres sent fœcuro
king Solomon.

BATHRUM, a name given by ancient geographers to a
kind of pool or bench proper for the reduction of dilute
waters. This is called Delphic Irenapheus, or the Hippocratic
well. Its description and use are represented at large by

BATHURST, Ralph, in Biography, born at How-
 thorpe, a small hamlet belonging to the parish of Thading-
worth in Northamptonshire, in the year 1630, received
the rudiments of his education at the free school in the
city of Coventry, where his prolegs in the Latin and Greek
languages was so rapid and extensive, that he was sent to Ox-
ford, and entered in Gloucester Hall (now Wadham Col-
lege), October the 10th, 1641, being then only fourteen
years of age. He was however soon removed to Trinity
College, where his father had educated him, and of which
two of his brothers, George and Edward, were then mem-
bers. Proceeding in his studies, he was elected scholar of
the college, June 5th, 1677. In January following he took
his degree of Bachelor of Arts; and in the year 1680, he
was appointed Fellow of the College. In 1681, he pro-
ceded Master of Arts; and in 1684, was ordained priest by
the bishop of Oxford; he inclinatory, was his biographer says,
deposing him to theological studies. Finding, however, from
the troubles that then, and for many years after, afflicted the
country
country, little prospect of advancing himself in that line, he applied to the study of medicne; which, in a letter to a friend some years after, he called "his refuge in bad times, and not his primitive design." But his mind was vigorous, he soon acquired considerable eminence in this profession; being assisted in his endeavours by Dr. Thomas Willis, with whom he kept up an intimate connection until death deprived him of that valuable friend. In 1634, he took the accumulated degrees of Bachelor and Doctor in Medicine; but he had before so far signalized himself, as to obtain the appointment of physician to the sick and wounded of the navy, which office he performed to the satisfaction of the commanders of the ships, and of the admiralty. Quitting this situation, he returned and settled in Oxford; and, with his friend Dr. Willis, attended Abingdon market regularly every Monday, to give advice to such patients as applied. He was an associate with Mr. Boyle, Dr. Seth Ward, Christopher Wren, and various other persons, who met every week at the rooms of Dr. Wkins, to discuss philosophical subjects; which meetings led to the formation of the Royal Society in London, in 1662. A committee or branch of the society continued their meetings at Oxford for several years after, of which Dr. Bathurst was elected president in 1668. On the restoration of King Charles the Second, he quitted the practice of medicine, and refumed his theological studies. In 1663, he was made chaplain to the king; and the year following, president of the college, which was nearly rebuilt under his direction. The expense of the building was furnished in part by the college, part by subscriptions solicited by the doctor, and no small portion of it from his own fortune. About the same time he married the widow of Dr. John Palmer, warden of All Souls College; but had no children by her. In 1670, he was installed dean of Wells. This advancement was procured him by the duke of Devonshire, to whose notice he had recommended himself by an elegant copy of Latin verses to Mr. Hobbes, on his Treatise of Human Nature, which was printed with the volume. In 1675 he was made chancellor of the university, and was re-elected to that office the two following years, by which means he had opportunity of reforming many abuses which had crept into the institution, and of establishing many useful regulations which still continue to be observed. As he had contributed largely in rebuilding and beautifying his own college, and was the first in introducing Grecian architecture in Oxford, he now set about restoring St. Mary's church, which had suffered much during the protecrator. He subscribed 300 l. towards paving the choir with marble, and erecting an organ there. In 1691, he was nominated by king William and queen Mary, bishop of Bristol, with liberty to keep his deanery and headship of the college; but had the resolution to decline this noble offer, lest it should detain him, he said, too long from the university, and be the means of retarding the improvements he was making there, both in discipline and in the buildings. In the mean while his fame for proficiency in letters became so extended, that he corresponded with most of the first literary characters in the kingdom, who frequently submitted their works to his inspection and criticism before they were published. He was particularly instrumental in advancing Derham, the celebrated author of the " Aftrj," and " Physico-Theology," from obscurity and indigence; recommending him to the bishop of Salisbury, through whose means he was made perpetual vicar in the church at Stratton. As he was a strict disciplinarian, and regularly attended his duty both in the university and at his deanery, he had little leisure for undertaking any extensive works; accordingly, excepting his " Prélecções tres de Respiratione," we have only his " Orations" before the university, on his being appointed vice-chancellor, on laying down his office, and on a few other subjects; with some short poems. These however have been sufficient to establish his character as an elegant Latin scholar. He was very abstemious in his diet, and regular in taking exercise; and had the happiness of enjoying an almost uninterrupted state of good health until he was upwards of fourteen years of age, when his sight began to fail, and at length he became blind. Walking one day in his garden, the only amusement that remained to him after the failure of his sight, he had the misfortune to break his thigh bone, by what accident it is not said; which occasioned him excessive torture, and after languishing a few days, he died in 1704. His property, which was considerable, he had directed by his will to be disposed of in the manner he had expended a large part of his income in his lifetime; in donations towards improving his college; in books and medals to different libraries; in donations to the cathedral at Wells, and to the servants of the cathedral and of his own college. The remainder was left among his relations, who were numerous. His directions concerning his funeral, as being singular, and marking somewhat the disposition of the man, we shall transcribe, etc. Concerning the place and manner of my funeral (he says) I am not at all particular, but shall leave it to the discretion of my executor; except it shall please God to give me leisure and opportunity of ordering it at the time of my death, as occasion may then require: only I shall always desire, that it may be performed with all convenient frugality and privacy; and that my mouth and nostrils may be firmly closed up with a platter of Dutch, and my whole head wrapped in a cloth: and that I be buried without any cover to my coffin, only with a black pall of woollen stuff loosely nailed on, and hanging loose down." See Life of Ralph Bathurst, by T. Warton.

Bathurst, Allen, earl Bathurst, a nobleman not more distinguished by the elevation of his rank, than by his abilities and integrity as a statesman, and by the elegance of his taste and the variety of his accomplishments as a polite scholar, was the son of Sir Benjamin Bathurst, descended from an ancient family of Luneburg, residing at a place called "Batters," and settled in England in the time of the Saxons, at a place called "Batters Hurl," or Batters Grove, in Suffolk, whence the name; and born in Wiltshire, in the year 1634. At the age of 15 years, he was entered in Trinity College, Oxford, where he enjoyed peculiar advantages for improvement under his uncle, dean Bathurst, who was then president. Having availed himself in an eminent degree of these advantages, he commenced his political career as a senator in 1705, being chosen representative for the borough of Ginceling in Gloucestershire, which he served in two parliaments. Under this character he distinguished himself in the debates that related to the union of the two kingdoms, and vigorously supported this measure. He likewise concurred in the opposition planned by his two friends, Mr. Harley and Mr. St. John, against the duke of Marlborough and his adherents; and by his spirit and eloquence he was of great service to his party. At the same time he was duly sensible of the merit of those from whom he differed in political principles; and by his conduct toward lord Somers, both in and out of office, he preserved his lordship's esteem and friendship. In his opposition to the whig ministry, he appeared always in the highest estimation of his own mind; for after their dismission, he accepted himself under government, though his abilities and activity entitled him to notice, and his connection with the principal tones of that period might naturally have led him to expect some honourable office. 
able and lucrative preferment. However, his merit was re-
compened in 1711, by advancement to the dignity of a peer
of Great Britain, under the title of lord Bathurst, baron Ba-
thurt of Bathurst in the county of Bedford. Upon the
accession of king George I., the political friends of his lord-
ship were in disgrace, and some of them were actually ex-
posed to the prosecution of government; and yet his attach-
ment to them remained firm and unchangeable. He even
avowed his disapprobation of the treatment they suffered,
which he considered as severe and vindictive; and on this
occasion he is said to have observed, in strong and poignant
terms, "that the king of a faction was only the sovereign
of half his subjects." His zeal in defence of his friends
was manifested by his joining in the protests against the
attainder of lord Bolingbroke, and the duke of Ormond; and
by his opposing the prosecution, and concurring in the un-
animous acquittal, of lord Oxford. In 1716, he opposed the
septennial bill; and united with thirty peers in entering his
reasons for dissenting from it, as a violation of the constitu-
tion. From the commencement of the year 1718, he took
an active and distinguished part, for the space of twenty-five
years, in every matter of importance that came before the
upper house of parliament, and he steadily opposed the mea-
ures of the court, and the administration of sir Robert Walpole.

Lord Bathurst was a zealous advocate for bishop
Atterbury; and distinguished himself, in 1723, on the third
reading of the bill for inflicting pains and penalties on that
ingenious and celebrated prelate. In 1727, he opened the
debate on the king's speech, and strenuously opposed a war
with Spain, which then threatened the country. "What
(faid he) can we get by the war, if it be a successful one?
I'll fay it in one word, nothing. What can we lofe, if it be
unprosperous? I'll fay it in one word, in a syllable, all." In
the year 1731, he supported the bill against permitting
penitentiaries to fit in the house of commons; he moved an
addres to the king for discharging the 12,000 Heftian troops
in the pay of Great Britain; and in the next parliament,
he very ably refuted the undue taxation of the poor, on the
bill for the revival of the salt-duty. On another occasion
he displayed his parliamentary talents, by the support of
the earl of Oxford's motion for reducing the number of forces
to 12,000 effective men, and vindicated the expediency and
usefulness of a national militia, as the most proper and con-
stitutional mode of defence in a free country. In a subse-
quent debate on the mutiny bill, his lordship declared him-
self, with great eloquence and spirit, against a large flan-
ding army, and in favour of a national militia. Among other
things, lie particularly urged the importance of all men in
the kingdom, or at least all freeholders, farmers, and sub-
tantial merchants and tradesmen, providing themselves with
arms, and training themselves to military discipline. He
likewise declared his utter disapprobation of the method
that had been adopted of alienating the finking fund, and
applying it to other objects besides the payment of the pub-
lic debts. Lord Bathurst was uniform and active in oppos-
ing the measures of sir Robert Walpole's administration,
particularly with regard to the transactions that regarded
the Spanish depredations, and the convention with Spain,
and the subsequent conduct of the war with that kingdom;
and he exerted himself, with fingular ability, in the debate
that lasted two days, on the question, whether an address
should be prefented to the king for the removal of this mini-
ister's influence, on majesty's preference and councils for ever.
When his lordship had accepted a place, in conjunction
with some of his friends, his reafoning, in 1743, in vindica-
tion of the propriety and necessity of retaining the Han-
overian forces in the service of England, was somewhat differ-
ent from the sentiments he had avowed on a former occa-
sion; but he was probably led to approve and defend this
measure by the critical situation of our foreign affairs, and
argued in its favour from a conviction of its prudence and
rectitude. Whatever opinions may be entertained of lord
Bathurst's political principles, and of the general reasons
upon which his opposition to the whig ministry was found-
ed, the history of that period will furnish scarcely any char-
acter, in which we may discover less discrepancy of con-
duct than in that of his lordship. We had close this brief
recital of his political history with the testimony of an ano-
nymous writer, who delivered it at a time in which his ta-
lents were in their full exertion and display. "Lord Ba-
thurft, in all he says, carries along with him that conviction
which arises from a warm sense of liberty and virtue, direct-
ed by great abilities and a most exquisitely distinguished.
He was called to the house of lords by means of the Tory in-
terest, upon a particular exigence of state; and therefore it
might have been prefixed, that he was entirely devoted to
that party. Yet he has chosen his principles of government
so happily from what is commendable in both parties, that,
upon whichsoever side he speaks, he is always observed to
lean to the extremes of neither."—Gent. Mag. vol. x. p. 103.

Lord Bathurst was married, in 1704, to Catherine, daugh-
ter and heirs of sir Peter Apley, by whom he had four
sons and five daughters. Having resigned, in 1744, the offi-
cce of captain of his majesty's band of gentlemen pensioners,
to which he was appointed in 1724, his lordship was in no
public employment till the year 1757, when he was ap-
pointed treasurer to the present king, prince of Wales,
in which office he continued till the death of George II.
At his majesty's accession in 1760, he declined the accept-
ance of any employment on account of his age; but in con-
consideration of his distinguished merit, he had a pension on
the Irish establishment of 2000l. a year. "As his lordship's a-
ilities and integrity," says an impartial and candid biogra-
pher, "in public life, gained him the esteem even of his political opponents, so in private life, his humanity and be-
nevolence excited the affection of all who were honoured
with his more intimate acquaintance."—"To his other vir-
tues lord Bathurst added all the good-breeding, polite-
necs and elegance of social intercourse. No perfon of rank,
perhaps, ever knew better how to unite "Otium cum dig-
nitate." The improvements he made round his seat at Ci-
rencelder were worthy of his fortune, and showed the gran-
deur of his taste." In this respect Mr. Pope (Works,
vol. ii. p. 170. ed. 1776.) paid him a just and fine com-
pliment:

"Who then shall grace, or who improve the foil?
Whos plants like Bathurst, or who builds like Boyle?"

The same excellent poet, in his epistle to Lord Bathurst on
the use of riches, has no less justly expressed his lordship's
knowledge of the right mode of employing a large for-
tune:

"The fence to value riches, with the art
'T enjoy them, and the virtue to impart,
Not meanly, nor ambitiously purfued,
Not funk by floth, not raised by fervitude;
To balance fortune by a julf expence,
Join with economy, magnificence;
With splendour, charity, with plenty, health;
Oh teach us, Bathurst, yet unfpoil'd by wealth;
That secret rare, between the extremes to move,
Of mald good-nature, or of mean felf love."

His lordship's wit, taste, and learning led him to seek the
acquaintance of men of genius; and he was intimately con-

BATH

nestled with the eminent personages of this character who adorned the beginning of the last century. From the few letters of his lordship that have been published, it appears, that his correspondence was a real honour and pleasure to those who enjoyed it. To the close of his life he preserved his natural cheerfulness and vivacity; and he was always accessible, hospitable, and benevolent. He was fond of rural amusements; and enjoyed, with a philosophic calmness, the shade of the trees which he had planted. Till within a month of his death, he constantly rode out two hours in the morning, and drank his bottle after dinner, jocosely observing, that he never could think of adopting Dr. Cadogan's regimen, as Dr. Cheyne had advised him fifty years before, that he would not live seven years longer, unless he abridged himself of his wine. About two years before his death, he had a party of friends; and being about to part with them at an early hour in the evening, when his fon, the chancellor, wished to retire, he said to his companions in a sprightly manner, as soon as his fon was gone, "Come, my good friends, since the old gentleman is gone to bed, I think we may venture to crack another bottle." In 1772, his lordship was advanced to the dignity of earl; and having lived to see his eldest surviving son several years lord high chancellor of Great Britain, and promoted to a peerage by the title of baron Aplly, he died in the 94th year of his age, after a few days' illness, at his seat near Crewe Castle, on the 16th of September, in the year 1775. Dibb. Brit.

BATHUS, in Entomology, a species of Papilio (Papilio. R. R. R.), with entire black wings, glossed with blue; beneath white, with numerous black dots, and a continued fulvous band. Fabricius. Inhabits Antria. This is Pa-

pìlìo Bathyllus Schreb. and Papìlo Bathyllus Schreb. BATHYCHRUS Cator, in Paining, a term used by the Greeks to express what the Romans call aestus: colour. Such a colour was coarse and dull, and wanted the life of the florid colours. See Exanthà Colores.

BATHYCOLPUS, in Ancient Geography, a bay and river of Europe, in the Thracian Bosporus. Hebychus.

BATHYLLUS, and PYLADES, in Biography, the inventors of a new method of representing all kinds of theatrical pieces by dancing. Bathyllus was a freedman of Maccenas, the object of his extravagant and licentious attachment; and in compliance with the wishes of Maccenas, Augustus connived at their plays and their art. Bathyllus excelled as a comic, and Pylaides as a tragic pantomime. They flourished under Augustus, about the year B.C. 18. From these two competitors for public fame in the respective departments of their art sprung two sects, each of which retained the name and preserved the manner and character of its master. The disciples of Bathyllus were called Bat-

thylli, and those of Pylaides were denominated Pylaides. The Romans divided themselves into parties on account of these two pantomimes; and the interest of Bathyllus's was at one time in pre-eminence as to procure the banishment of Pylaides. Upon his return Augustus recommended his behaving better for the future, and not attempting to divide the people into parties or factions. Pylaides replied, "Caesar, it is of service to you to have the people buffs about Bathyllus and me." Gen. D. C. Crev. Hist. 1. 1. p. 132.

BATHYLLUS, in Ancient Geography, a fountain of Arcadia, in the Pempeutice, near Megalopolis. Paufianias.

BATHYMIL, a people of Arabia Felix. Ptolemy.

BATHYS, a river of Phrygia Salutaris, which flowed in the north of this province, along the plain of the city Dorylaeum, and discharged itself into the river Sangaris.

BATHYS, Flumè Tavurom, a river of Sicily, which ran into the gulph of Calèl a Marc.

BATIAS, the name of a port of Ethiopia. Ptolemy.

BATIA, a people of India, on the other side of the Ganges. Ptolemy.

BATIA, a town of Italy, in the territory of the Sabines.

BATI, a district of Attica, belonging to the tribe of Eóides.

BATIÈ, a town of Epirus.

BATIANA, BAIX, a town of Gaul, on the right side of the Rhine, according to M. d'Asville.

BATIANI, a people of Italy, placed by Ptolemy in Langued.

BATUS, a musical instrument made of metal, in the form of a staff, furnished with metallic rings, which being struck yielded a kind of harmonical sounds; used by the Armenians in their church-service.

BATINA, in Ancient Geography, a town of Asia, in Medo. Ptolemy.

BATINUS, a town of Italy, in Piccinum.

Species, 1. B. moratima. Sloa. Jan. 1. 144. Kali. This is a thorn about four feet high; stems bristie, round, ashcoloured, branched, diffused, procumbent; young branches, four-cornered, four-furred, green, oppoite and upright; leaves oblong, acute, drawing to a point towards the base, flatly, fuscic; flat above, convex beneath, fuscic, opposite, scarcely an inch long, numerous; stigma white; fruits yellow or greenish-yellow. The whole plant is very tall to the talie, and is barbed for barilla at Carthagena, &c. A native of the Caribbe islands and the neighbouring continent; very common in all the Clint marlies on the south side of Jamaica. Linnæus doubts whether it be distinct from the Lupbenal of Plinther. Martyn's Miller's Dict.

BATIS, in Entomology, a species of PhalaEna, found in England and some other parts of Europe. The interior wings are brown, with five rose-coloured spots on each; posterior ones whitish. This is a rare and elegant insect, and is called by collectors of Englibh insects the peach-blossom moth. Linn. Donov. Brit. Inf. &c.

BATIS, in Ethnology, a species of Raja, called in England the Skate. It is varied; back fom th in the middle, with a finge row of spines on the tail. Linnæus.

This is the largest fish of the Ray tribe; it inhabits all the northern parts of Europe in immense quantities, though it is certainly less common than the thornback, with which it is sometimes confounded. The usual size is from two to three feet in length, or rather more, including the tail; and they have been taken of the weight of an hundred and fifty

5 R 2 or
or two hundred pounds. They couple in March and April, and spawn in May. The flesh of the skate is thought better than that of the other Rays.

BATISTANI, in Ancient Geography, a people of Spain, who inhabited the northern part of Baetica.

BATISTE, in Commerce, a fine white kind of linen cloth, manufactured in Flanders and Picardy.

There are three kinds of battle: the first very thin; the second left thin; and the third much thicker, called Holland battle, as coming very near the coastlands of Holland. The chief use of battle is for back-charts, head-charts, surphers, &c.

BATMAN, a weight in Turkey, consisting of six okes. For one of these batman make a carver's yard, and amount to about seven hundred and twenty pounds English weight.

Batnir, or Batnir, is of a weight used in Turkey and Persia. The Turkish batman is of two kinds: the larger containing six okes, or ocques; at three pounds three quarters Paris weight the ocque; so that the batman amounts to about twenty-two Paris pounds and a half; the smaller, composed likewise of six ocques, at fifteen ounces the ocque, amounting to five pounds ten ounces.

The Persian batman is likewise of two kinds: one called the 'Ega's weight, la- man de Ega, or Ega, used for weighing most of the necessaries of life, equivalent to about twelve pounds and a half Paris weight; the other called leman of Tauris, equal to six pounds four ounces Paris or Amsterdam weight. These, at least, are the proportions given by Tavtrier. Chardin rates the Persian batman somewhat lower, viz. the former at twelve pounds twelve ounces; and the latter at five pounds fourteen ounces.

BATMANSON, John, in Biography, prior of the Carthusian monastery, or Charter-house, in London, in the 16th century. He studied at Oxford; and being a great favourite of Edward Lee, archbishop of York, wrote at his request against Erasmus and Luther. He died in 1531, and was buried in the Charter-house. Bale represents him as proud, arrogant, and fond of wrangling; and says, that Erasmus flays him an ignorant fellow, and vain-glorious even to madness. Pits, on the other hand, commends his genius, learning, piety, and zeal; his acquaintance with the scriptures, and his highly exemplary life. His works are "Animadversions in Annotationes Erasimi in N. T."; "A Treatise against some of Luther's writings;" both these he afterwards retracted: "Comment in Prover. Solomon," etc. in Cantica Canticum: "De Unio Magna," etc. in Institutiones Novi Test. "De Contemptu Mundi," "De Chribo du Boeunt," a homily on Luke ii. 42; and, "On the words Alisne efi, &c." B. G. Br. Gen. Dict.

BATNE, in Ancient Geography, a town of Mevrotamia, in Osdrome. Ammianus Marcellinus calls it Batne and Batare, and says, that it was a municipal city of Antiochus, of great trade, built by the Macedonians, at a small distance from the Euphrates. The emperor Julian made it a place of defence by encompassing it with walls. Procopius calls it a small and obscure town, and says, that it was about a day's journey distant from Edessa. It lay south of Edessa, and east of Zeugma. It was reduced by Trajan, who took it from Choraces, king of the Parthians.

Batne was also a small town of Syria, situate between Berea and Hierapolis, pleasantly seated in a grove of cypress, about twenty miles from the latter city. When Julian visited this town, A.D. 353, the solemn rites of sacrifice were decently prepared by the inhabitants, who feem attached to the worship of their tutelar deities, Apollo and Jupeter.

Batnir, or Batinda, in Geography, a town of Hindostan, in the county of Moultan, in a district famous for pastures and fine hores. Timur marched from Adjodin, a town included in one of the large islands formed by the branches of the Selenge, to Batnir, the distance of 600 miles, 500 miles being equal to about 95 British miles; and in his way he crossed an extensive defile; so that Alexander was not misinformed when he was told there was a defile beyond the Hyphasis. After taking and destroying Batnir, represented as a very strong place, which, however, employed only a few days, he marched by a circuitous road to Sumatra, directly distant from Batnir only 72 geographical miles. Batnir is about 170 miles E. S. E. of Moultan, and 170 N. W. of Agrimusc. N. lat. 29° 15'; E. long. 74° 30'.

Bato, a river of Italy, in the kingdom of Naples, which runs into the Mediterranean, 2 miles S. E. of Scala, in the province of Calabria Citra.

BATOA, a small island near the west coast of Sumatra, seated very nearly under the equinoctial line. E. long. 98°.

BATOE, Ibn Batoe, long Abes; & Ibn Pampis Cambolus, names given by Valent. in his work on Indian fishes, to the species of Chetodon, specifically called Annularis by Grinl.

BATON, or Baton, in Heraldry. See Baton.

Baton, or Bifion, as an instrument of punishment. See Bistolado.

Baton, Fr. in Musc, a musical character for slenderness, during two bars in alla breve time, and four & common and triple time. It fills up two spaces of the five-line staff; and has a 2 or a 4 placed over it, proportioned to the time of the movement. See Breve, Time-Table, and Rests.

BATOONS of St. Paul, Bajloncini di San Paolo, in Natural History, a name given by some of the Italian writers, as Angustino Sicilia and others, to the lizards jadali, or other species of echini. These are found in vast abundance in the island of Malta; and some every thing there is commemorated with some title, with St. Paul at the end of it, these are called boschi di Pastoral. or St. Paul's batoons.

BATOPILAH, in Geography, a town of North America, in the province of New Navarre, 120 miles north of Cinamon.

BATOS, in Ichthyology. See Batis.

BATRACHIA, in Ancient Geography, a town of Afia, in Sarmatia. Ptolemy.

BATRACHIAS Lapis, the frog stone, a name applied by different writers to two very different substances; some understanding by it lumps of common flint, which have accidentally formed themselves into this figure; and others, those pieces of amber, which contain either a whole frog, or any part of one.

BATRACHITES, among Ancient Naturalists, a kind of gem found in Egypt, denominated from its resemblance in colour to a frog. The word is formed from βατράχον, rana, a frog. Linny speaks of three flones under this denomination; nam ranæ fimbriam coloris, alterium eburni (or rather, according to Hardouin's correction, æburni), tertium rubentis et nigri. The batrachites differed from the modern bufonites, which does not appear to have been known to the ancients.

BATRACHOIDE, in Ichthyology, a genus of fishes of the Jugulares kind, established by Lacépède for two fishes; the one belonging to the Gadus, and the other to the
the Blemys, genera of Linnaeus, viz. G. lat. and B. rufus. The character of the blemys consists in having the head very large and greatly depressed; opening of the mouth very spacious; and one or more beards situated about or on the upper lip. - See BLEMYS.

BATRACHOMYOMACHIA, a poem, by Homer. Geography, vol. i. pp. 114, 115. See BATTALION.

BATRACHUS, a species of Silurus, found in Asia and Africa. The dorsofin is single, and contains sixty rays; beards of the mouth eight. Linn. Mus. Fr.—The tail is entire.

BATTA, or Batta, in Geography, a duchy or province of Africa, situate on the south-west of Pango, and having Dumbo, Amulissa, and the salt-peat mountain on the east, on the south the marquise of Inculls, and the burnt mountains, and Congo and Fumba on the west. It is of considerable extent, was formerly called Anguirima or Aghirumba, and was a kingdom of itself, till both king and people submitted to the kings of Congo. This country is generally fertile, well-watered by rivers, and produces several sorts of grain. The inhabitants are more civilized than their neighbours.

Batta, the capital of the above duchy, is distinguished in no other respect besides the fertility of its territory, and its being the residence of the governors of this province. There are allowed to have a number of archbishops in pay, to defend it from the incursions of the wild Giajas, or Jaga, who inhabit the districts near its eastern frontiers, beyond the mountains of the Sun and Salkpeter, and who chiefly infest by ravaging the adjacent territories. The road between this capital and that of the kingdom of Congo, called St. Salvador, has, it is said, a great number of houses and hamlets on both sides.

Batta, the name of a country in Sumatra, where the English have two settlements. The inhabitants still eat human flesh, but restrict themselves to that of prisoners taken in war, and capital offenders.

BATTABLE GROUND, denotes land lying between England and Scotland, of which the right of possession was disputed, when they were two distinct kingdoms.

The word imports as much as litigious, or disputable ground, from battre, to beat or fight.

BATTACKS, or Battages, a punishment in Russia, similar to the battado, or batallado, of China, Turkey, &c. The delinquent is stripped naked, and made to lie on his belly, while two executioners beat him with small sticks, till the judge cries out, "enough." The order to beat is frequently not given till the back of the unfortunate sufferer has been mostly mangled. During the whipping, he is obliged to pronounce the word "Winawat," which means "I am guilty," and at the end of the punishment he must go and kiss the feet of him who directed it, and thank him that he did not make it more severe. The highest lords are not exempted from the battages, and the sentence is set on their unhappy heads. This punishment is particularly reserved for the inferior orders, whom malversation or rogosity would have nowhere else driven from their employments. In Russia, it is reckoned sufficient to reduce them to an inferior employment, after the commission of the battages. Chantreus's Travels in Russia, vol. i. p. 117. See BASTONADO.

BATTAGLIA, in Geography, a town of Italy, in the kingdom of Naples, and province of Capitanata, 3 miles N.W. of Velle.

BATAIL, in Ancient Geography, a promontory of Arabia, north-west of Jofa Cemara.

BATTAIL, an army ranged in order of battle, or ready for engagement.

In this sense, we meet with the depth of a battalia; to march in battalia, with the baggage in the middle; to break the battalia, &c. In the Roman battania, the Battail made the front.

BATTALION, in the Military Art, signifies a small body of infantry, arranged in regular order, and instructed to march and to act in concert.

There are different opinions respecting the force of which a battalion should consist. If composed of too great a number of men, it cannot perform its evolutions with the necessary facility; if, on the contrary, the troops are not sufficiently numerous, it is incapable of producing by its attack any considerable effect. The number must therefore be so regulated, as to permit the necessary movements to be executed with promptitude and regularity; and at the same time, to compose a solid body, capable both of charging with firmness, and of fulfilling the different offices in which it may be opposed without falling into disorder.

The number of the battalion varies according to the situations of belligerent nations, their arms, the manner in which they employ those arms, and the order in which they engage. Europeans formerly differed very widely on all these points; but at present all the continental powers, the Turks alone excepted, observe nearly the same dispositions with respect to the battalion. The term even is adopted in every modern language.

The French have fixed the number of the battalion at about 700 men. Some nations form them still stronger, others weaker. In the English service they usually consist, in time of war, of ten companies; forming, exclusively of the flanks, a total of between seven and eight hundred. When employed on service, the battalion being filed up at the commencement of a campaign, and rarely recruited till its close, are seldom or ever complete; as well from the losses they suffer in different engagements, as from the sickness and other accidents inseparable from the military profession.

The arms of the battalion have been frequently and materially altered. In the infancy of modern tactics, one third of the troops were furnished with pikes, and drawn up in the centre; the other two thirds carrying musquets, were posted on the wings, to flank, protect, and second, by their fire, the onset of the pikes. The infantry are now universally armed with firelocks and bayonets, the use of the pike being completely laid aside.

The modern method of arrangement has been decreed by the
the ingenious chevalier de Folard (Traité de la Colonne, p.7) as rendering the battalions too shallow, weak, incapable of supporting each other, and exposing them to be easily penetrated and broken through, all which he denominates essential faults in tactics. According to him, the real strength of a corps consists in its thickness, or the depth of its files, and their connection and plaine, this rendering the flanks almost as strong as the front. He even lays it down as a maxim, that every battalion arranged deeply, and with a solid front, will defeat another much stronger than itself disposed according to the usual method. In fact, a corps whose front is widely extended, and whose depth is but small, manoeuvres with more difficulty, and cannot totally avoid that wavering from which the close order of M. Folard's battalion or column renders it comparatively exempt. The opinion of the Chevalier has been in a great measure adopted by his countrymen, though his theory has been violently attacked by two French officers formerly in the service of the States General. They admit the superior strength of the column to the modern battalion, were the action to be decided with pikes and swords; but maintain that where fire-arms are used, M. Folard's column is but ill calculated for the purpose, and must be infallibly destroyed. The late campaigns in Italy furnish the bolt commentary upon his superciliousness.

BATTALION, Square, is a battalion the files of which are equal to the ranks, and whose files form an equal front. There are two kinds, the solid, and the hollow: in the former, the ordinary intervals between the ranks and files are the only ones preferred; in the latter, a vacant space is left in the centre, of pretty considerable extent, according to the ground occupied by the battalion. We shall presently give some account of the evolutions necessary in forming both kinds of the square.

The solid square, however ingenuous in its formation, and respectable in its appearance on a field of exercise, is of very little utility in actual service. In the first place, it suffers prodigiously from the fire of the enemy, especially if artillery is brought to bear upon it; in the second, it is next to impossible for the troops in the centre of the battalion to employ their own fire effectually. M. de Folard, in his treatise de la Colonne, exposes much at large the defects of both the solid and the hollow square. He indicts, however, recommends their use; his own column being nothing more than two or three battalions drawn up according to the rules of the solid square, and placed without any intervals in the rear of each other. Regarding, however, the solid square as entirely unfit for the column, of which we shall speak more at large in its proper place, we shall here conclude by observing that the only case in which it seems capable of affording any real service is when opposed to an enemy whose forces confine entirely of cavalry.

The hollow square, which claims for its inventor the celebrated prince Maurice of Nassau, is much less usefully in its movements, sooner formed, and more easily reduced, than the solid. Its fire too is more regular, better directed, and does much greater execution. It however partakes in a great measure of all the disadvantages of the solid square, and its use can only be recommended in cases of the last extremity, or, as above, when opposed to cavalry.

BATTALION, Triangular, is a body of troops disposed in a triangle, whose ranks, augmenting equally, form an arithmetical progression. Many skilful officers have preferred it to the square, from its presenting a greater front, and being able to make head on all sides. The difficulty is to ensure soldiers to march in this order; and we may conclude the triangular only preferable to the square battalion in close action, when it is necessary to preserve an extended front, or when the nature of the ground requires such a disposition.

BATTALION, Round, is that in which the ranks form a number of concentric circles. The Romans made frequent use of this manoeuvre in cases of emergency, and were very perfect in its execution. Cæsar's commentaries furnish several examples, especially on occasion of the defeat of Sabinus and Cotta by Ambocius, where the formation and nature of the orb are very satisfactorily elucidated. (De Bell. Gall. lib. v.) But in the battle between Cæsar and Labienus in Africa, translators seem to have mistaken for the orb, a disposition perfectly different. (Hirt de Bello Afr.)

Although recommended by M. de Puyfécourt, the round as well as the triangular battalion are now generally disdained.

At a crisis like the present, we trust the following account of the training the recruit for service, the order and formation of the battalion, and the principal evolutions it is designed to execute, will not prove wholly unacceptable to our readers. Care has been taken to render the narration as little tedious as possible, and as concise as may be consistent with periphrasis.

Drill of the Recruit without Arms.

It requires in the instructions to whom this duty is entrusted, and who are to be serviceable for the reception and instruction of the corps, an accurate knowledge of the subject, and a clear and concise method of conveying instruction, united with a firmness capable of commanding perfect attention to their directions. They must allow for weaknesses of capacity in the recruit, be patient and not rigorous where endeavour and good-will are not wanting, as quickness is only to be acquired by much practice. Officers and instructors must be critically exact in their own commands, as well as in observing the execution of what they require from others. Without this, all labour will prove ineffectual, and the proposed discipline never be attained.

The recruit must be taught progressively to comprehend one thing before he proceeds to another. In the first circumstances of postion, his single, flegers, elbow, &c. are to be justly disposed by the instructor. When more advanced, recruits should not be touched, but from example and directions be taught to correct themselves when admonished. They should not be kept too long at any particular part of their exercise, so as to fatigue or render them unsteady; and marching without arms ought to be much intermixed with the use of the fire-lock. Yafe, or mufic, must on no account be used. The young soldier is to be confirmed by habit alone in that cadence of step he is afterwards to maintain in marching to the enemy in spite of every variety of noise or circumstance which may tend to derive him.

Each recruit must be trained finely, and in squad, as hereafter described; nor until he has been in various points of his duty, is he to be allowed to join the battalion, which is sensibly incommoded by the awkward behaviour even of one man. On return from long service, every folder must be re-drilled before he can again join his company.

1. Position of the Soldier. The equal squareness of the shoulders and body to the front is the first and great principle of the position of a folder. The heels must be in a line, and closed; knees straight, without slightness; toes a little turned out, so that the feet may form an angle of about forty degrees; the arms are to hang near the body, but not stiff, the flat part of the hand and little finger touching the thigh; the thumbs as far back as the seams of the breeches; elbows and shoulders to be kept back; the belly rather drawn in, and the breast advanced, but without constraint; the body upright, but inclining forward,
BATTALION.

ward, so that its weight principally bears on the fore-part of the feet; the head to be erect, and turned neither to the right nor left. The position in which a soldier should move, determines that which he is to observe when standing still. No method must be left untried to suppress the limbs, and banish the air of the ruffle. But that exactness of position which refines the person, and tends to throw the body backward instead of forward, is contrary to every true principle of movement, and must therefore be most carefully avoided.

II. Standing at ease. 1. On the word Stand at Ease, the right foot must be drawn back about six inches, and the greatest part of the weight of the body be brought to bear on it; the left knee a little bent, the hands brought together before the body; but the shoulders to be kept back and square; the head to the front, and the entire attitude without constraint. 2. On the word Attention, the hands are to fall smartly down the outside of the thighs; the right heel to be brought up on a line with the left, and the proper position of a soldier to be immediately resumed. After standing at ease for any considerable time in cold weather, the men may be permitted, by command, to move their limbs, but without quitting their ground, so that on the word Attention, no one shall have materially lost his dressing in the line.

III. Eyes to the right, &c. On the word Eyes right, glance the eyes to the right, with the right foot possible turn of the head; Eyes left, turn them in the like manner to the left; Eyes front, the look and head are to be directly to the front, the habitual position of the soldier. These motions are only useful on the wheeling of divisions, or when dressing is ordered after a halt. Particular attention must be paid, in the several turnings of the eyes, to prevent the recruit from moving his body, which should be preferred perfectly square to the front.

IV. The Facing. In going through the facing, the left heel never quits the ground; the body must rather incline forward, and the knees be kept straight. At the word, to the right, face, first, place the hollow of the right foot smartly against the left heel, keeping the shoulders square to the front; second, raise the toes, and turn to the right on both heels. To the left, face; first, place the right heel against the hollow of the left foot, shoulders square to the front; second, turn, as before, to the left on both heels. To the right about, face; first, place the ball of the right toe against the left heel, shoulders square to the front; second, raise the toes, and turn to the right about on both heels; third, bring the right foot smartly back, in a line with the left. To the left about, face; first, place the right heel against the ball of the left foot, keeping the shoulders square to the front; second, turn, as before, to the left about; third, bring the left foot smartly up, in a line with the left. The utmost precision must be observed in the facing, for if they are not exactly executed, a corps, although previously properly dressed, will lose their dressing on every small movement of facing.

V. Position in Marching.—March! The soldier must here, as much as possible, maintain the position of his body, as directed in feet. I. He must be well-balanced on his limbs. His arms and hands without stiffness, must be kept steady to his sides, and not suffered to vibrate. He must not llop forward, still less lean back. His body is to be kept square to the front, and thrown rather more forward in marching than when halted, that it may accompany the movement of the leg and thigh, which movement must spring from the haunch. The ham must be stretched, but without flatening the knee. The toe a little pointed, and kept so near the ground, that the shoes-soles may not be visible to a person in front. The head to be kept up, Davis to the front, and the eyes not suffered to be cast down. The feet, without being drawn back, must be placed flat on the ground.

VI. Ordinary Step. The length of each pace, from heel to heel, is 30 inches, and the recruit must be taught to take 75 of these leaps in a minute, without tottering, and with perfect headsets. Ordinary time being the pace on all occasions whatever, unless greater celerity be particularly ordered, the recruit is to be carefully and thoroughly trained to this most essential part of his duty, and made perfectly to understand, that he is to maintain it for a long time together, in line, in column, and in marching over rough or smooth ground. This is the flowell leap which a recruit is taught, and is also applied in all movements of parade.

VII. The halt. On the word, halt, let the rear foot be brought upon a line with the advanced one, so as to finish the leap which was taking when the command was given.

VIII. The oblique Step. Having acquired the regular length and cadence of the ordinary pace, the recruit is next to be taught the oblique leap. At the word, to the left, oblique march! he will, without altering his squarings of position, when he is to turn, with his left foot, and point, and carry it forward 15 inches, in the diagonal line, to the left, which gives about 13 inches to the side, and nearly the same number to the front. On the word two, he will bring forward his right foot 30 inches, thus placing the heel of that foot 13 inches directly before the left one. Here he will pause, and on the word two, continue the same mode of marching, by advancing his left foot 30 inches, pausing at each leap, until confirmed in his position, as it is essentially necessary to take the greatest care in preferring the shoulders square to the front. Combining these two movements, the obliquity gained will amount to an angle of about 25 degrees. When the recruit is habituated to the leap, he must be made to continue it firmly, without pausing, and in the cadence of the ordinary pace, viz. 75 leaps in the minute. As all marching (the flip-leap excepted) commences by the left foot, whether the oblique commences from the halt, or on the march, the first diagonal leap taken, is by the leading foot of the side inclined to, when it comes to its turn, after the command is pronounced. Squareness of person, and the habitual cadenced leap are, consequently, the great directions of the oblique, as well as the direct march.

Each recruit should be separately and carefully instructed in the principles of the foregoing eight sections of the drill. They form the basis of all military movements. Three or four recruits will now be formed in one rank, at very open files, and instructed in the following manner.

IX. Drilling when halted. Drilling is taught equally by the left as by the right. On the word drill, each individual will call his eyes to the point to which he is ordered to drill, with the smallest turn possible of the head, but preserving the shoulders and body square to the front. The whole perfom of the man must move as may be necessary, and bending backward and forward is not permitted. He must take short, quick leaps, thereby gradually and exactly to gain his position, and on no account be permitted to attempt it by any sudden or violent alteration, which will infallibly derange whatever is beyond him. The faces of the men, not their breasts, or feet, are the line of drilling. Each soldier is to be able just to distinguish the lower part of the face of the second man beyond him. In drilling, eyes are always turned to the officer who gives the word; who is polled at the point by which the body halts; and who from that point corrects his men on another, at or beyond
the opposite flank. Faults to be avoided, and generally committed in drilling, are, pesling the line; the head forward, and body kept back; shoulders not square; or the head turned too much.

Two or more men being moved forward, or backward, a given number of paces, and placed in the new line and direction, the following commands will be given: 1. by the right (or left) forward-drift ; 2. on the right (or left) backward-drifts. The drifting once accomplished, eyes front will be given, that heads may be replaced, and remain square to the front. No rank, or body, ever should be drifted, without the officer on its flank determining a line on which to form it, and to that purpose taking as his object the distant flank man, or a point beyond him, or a man purposely thrown out. Drifting must then be made gradually, and progressively, from the fixed point, towards the distant flank one; and each man successively, but quickly, must be brought up into the true line, so as to become a new part, from whence the instructor proceeds in the correction of the others; and himself, while thus occupied, must take care, that his person, at least his eyes, be in the true line, which he is then giving.

X. Stepping out. The squad marches, as already directed, in ordinary time. On the word, step out, the recruit must be taught to lengthen his step to 33 inches, by leaning forward a little, but without altering the cadence. This step is necessary, when a temporary exertion in line, and to the front, is required; or when the rear divisions of a column are to move up in line with the leading ones, and is applied both to ordinary and quick time.

XI. March time. On this word, the foot then advancing completes its pace. The cadence is then continued, without gaining any ground, but alternately throwing out the foot, and bringing it back square with the other. At the word, ordinary time, or forward, the usual pace of 30 inches will be taken. This step is necessary marching in line, when any particular battalion is advanced, and has to wait for the coming up of others.

XII. Stepping short. On the word, step short, the foot advanced will diminish its pace, and afterwards each recruit will step as far as the ball of his toe, and no farther, until the word, forward, be given, when the usual pace is to be taken. This step is useful when a momentary retardation either of a battalion in line, or of a division in column, is required.

XIII. Changing the Feet. To perform this in marching, the advancing foot completes its pace, and the ball of the other is brought up quickly to the heel of the advanced one, which instantly makes a step forward, so that the cadence may not be lost. This is required of an individual who may be stepping with a different foot from the rest of his division; in doing which, he will, in fact, take two successive steps with the same foot.

XIV. Side, or closing Step. This is performed from the halt in ordinary time, at the following command; Close to your right, or left (a caution)—March! On the latter word, eyes are turned to the right, and each man carries his right foot about 12 inches directly to his right; or, if the files are closed, to his neighbour's left foot, and instantly brings up his left foot, till the heel touches his right heel; he then pauses, so as to perform this movement in ordinary time, and proceed to take the next step in the same manner; the whole with perfect precision of time, shoulders kept square, knees not bent, and the true line on which the body is formed.

At the word halt, the whole halt, turn their eyes to the front, and are perfectly steady.

XV. Buck Step. This is performed in the ordinary time and length of pace, from the halt, on the command step back

---March! The recruit must be taught to move straight to the rear, preferring his shoulders square to the front, and his body erect. On the word halt, the foot in front must be brought back square with the other. A few paces only of the back step can be necessary at a time.

XVI. Quick Step. The cadence of the ordinary step having become perfectly habitual to the recruits, they are now to be taught to march the quick time, which is 108 steps in the minute, each of thirty inches, making 3200 feet in a minute. The word of command, Quick—March! is given with a pause between them. The word Quick, is to be considered as a caution, and the whole to remain perfectly still audibly. On the word March! the recruits step off with the left foot, keeping the body in the same posture, and the shoulders square to the front. The foot to be lifted from the ground, that it may clear any flints, or other impediments in the way, and be thrown forward, and placed firm. The whole of the sole to touch the ground, and not the heel alone. The knees are not to be bent, neither are they to be stiffened, so as to occasion fatigue or constraint. The arms to hang with ease along the outside of the thigh; a slight motion to prevent restraint may be permitted, but not to swing out, and thereby occasion the heel turn, or movement of the shoulder. The head is to be kept to the front; the body well up, and the utmost readiness to be preferred. This is the pace to be used in all filings of divisions from line into column, or from column into line; and by battalion columns of manoeuvre, when independently changing position. It may occasionally be used in the column of march of small bodies, when the route is smooth, and no obstructions occur; but in the march in line of a considerable body, it cannot prudently be required, nor often in a column of manoeuvres. Fatigue will otherwise arise to the follower, and more time be lost in hurry and inaccuracy than is attempted to be gained by quick steps.

N. B. The word March given singly, at all times denotes that ordinary time is to be observed. When the quick march is meant, that word will precede the other. The word March marks the commencement of movements from the halt; but is not given when the corps is in previous motion.

XVII. Quickest Step. The quickest time, or wheeling march, is 120 steps of 30 inches each, or 3000 feet, in the minute. The directions already given for the march in quick time are equally applicable to the march in quickest time. This is adapted chiefly to the purpose of wheeling, and is the rate at which all bodies accomplish their wheels; the outward file stepping 33 inches, whether the movement is from line into column, or column into line. In this time also divisions should double and move up, when passing obstacles in line, or when in column of march it becomes necessary to increase or diminish the front.

Three or four recruits in rank, with intervals of twelve inches between them, should be practiced in the various stops, that they may acquire the firmness and independence of movement. Many different times of march would only perplex the soldier: the three already mentioned must suffice. Plummets, which vibrate the required times of march in a minute, are of great utility, and can alone prevent or correct uncertainty of movement. They must be in the possession of, and occasionally referred to, by each instructor of a squad. The several lengths of plummets swinging the times of the different marches in a minute, are as follows:

Ordinary time, 35 steps in a minute, 54 inch. 96 hund. Quick do. 108 do. 12 3
Quickest do. 120 do. 9 80

A musket
A musket ball, suspended by a string which is not subjected to stretch, and on which are marked the different required lengths, will answer the above purpose, and should be frequently compared with an accurate standard. Accurate distances of steps may also be marked out on the ground along which the soldier is practiced to march, and thereby assist him to the just length of each.

Six or eight recruits will now be formed in a rank, at close files, leaving a steady well-drilled officer on their flank to lead; and file marching may be taught them.

XVIII. File Marching. The recruits must first face, and then be instructed to cover each other exactly in file, so that the head of the man immediately before may conceal the heads of all the others in his front. The drilled obedience of all the rules for marching is particularly necessary in marching by files, which is first to be taught the ordinary, and afterwards in quick time. On the word March, the whole immediately step off together, gaining at the very full step thirty inches, and continuing each step without increasing the distance between each recruit, every man backing or placing his advanced foot on the ground, before the spot whence the preceding man has taken up his. No looking down or leaning backward is to be tolerated on any pretense. The leader is to be directed to march straight forward to form contact object given him for that purpose, and the recruits made to cover another during the march with the most systematic exactness. Great attention must be paid to prevent them from marching with their knees bent, which they will at first be extremely apt to do, from an inattention to maintaining the heeled of those before them.

XIX. Wheeling in Single Rank, from the Halt. At the word to the Right Wheel, the man on the right of the rank faces to that flank; on the word March, they step off together, the whole turning their eyes to the left (the wheeling flank), except the left hand man, who looks inwards, and during the wheel, becomes a kind of guide-line for the rest to conform to and maintain the uniformity of front. The outward wheeling man always lengthens his step to thirty-three inches. The whole observe the same time; but each man shortens his step, in proportion as he is nearer to the standing flank on which the wheel is made. During the wheel, the step diminished, as they touch without incommending their neighbours; nor must they step forward, but remain upright. Opening out from the standing flank, and closing in upon it, during the wheel, are equally to be avoided. On the word Halt—Drill, each man halts immediately, without jumping forward or making any false movements. When able to perform the wheel with accuracy in the ordinary time, the recruits must be next practiced in the quickest. Nothing sooner tends to enable them to acquire the proper length of step, according to their distance from the pivot, than continuing the wheel without halting for several revolutions of the circle.

XX. Wheeling, in Single Rank, from the March. The recruits are first taught to perform this wheeling at the ordinary, afterwards in the quickest time, the proper wheeling step. The rank marching to the front in ordinary time, receives the word of command, Right—Wheel. The man on the right of the rank instantly halts, and faces to his right. The rest of the rank turning their eyes to the wheeling flank (as above directed), immediately change the step together to wheeling time. As soon as the portion of the circle intended to be wheeled is completed, the words Halt—Drill will be given, (a pause of two or three seconds may be made), and then March, at which the whole rank steps off together in ordinary time.

XXI. Wheeling backwards, in Single Rank. At the word On your Right, Backward—Wheel, the right-hand man of the rank faces to his left. At the word March, the whole step backward in wheeling time, drawing by the outward wheeling man, those nearest the pivot making their steps extremely small, and those towards the wheeling man increasing them as they are placed nearer to him. The recruit in this wheel must not bend forward, nor be suffered to look down; but by closing his eyes to the wheeling flank, preserve the drilling of the rank. On the word Halt, the whole remain perfectly steady, still looking to the wheeling flank, till they receive the word Right—Drill. The recruits should be first practiced to wheel backwards at the ordinary step. At all times it will be necessary to prevent their hurrying the pace, an error soldiers are very apt to commit, particularly in the backward wheel. Where large bodies wheel from line into column, this wheeling is necessary to preserve the covering of pivot flanks, and the distances of the interval, which the line has broken into.

XXII. Wheeling in Single Rank, on a movable Pivot. In performing this wheel, both flanks are moveable, and describe concentric circles round a point, which is removed a few paces from what would otherwise be the standing flank; and eyes are all turned towards the directing pivot man, whether he is on the outward flank or the flank wheeled to. When the wheel is to be made to the directing pivot flank (suppose the left), the rank marching at the ordinary pace, receives the word Right Shoulders Forward; on which the pivot man, without altering either the time or length of his pace, continues his march on the circumference of the lesser circle; and tracing out a considerable arch, on the principle of wheeling, gradually brings round his rank to the direction required, without obliquing the other flank, which is describing the circumference of a larger circle, to too great hurry. On the word Forward, shoulders are squared, and the pivot marches directly to his front. When the directing pivot is on the outward flank, and has to describe the circumference of the larger circle, on the word Left Shoulders Forward, he will (preferring the time and length of his pace) gradually bring round the rank to the required direction, so as to enable the inward flank to describe a similar arc of a lesser circle, concentric to the other. The pivot man, during this time, continues his march, on the circumference to which the rank marches to the proper pivot; and when he describes the smaller circle of the wheel, the other flank which has more ground to go over, will quicken its march and step out. When the pivot describes the greater circle of the wheel, the other flank having less ground to go over, will step shorter and gradually conform. In the first cafe, the recruit must be cautioned against opening out from the pivot; and in the latter, from crowding on him. The just performance of this mode of wheeling depends so much on the directing pivot, that a well-drilled soldier should at first be placed on the flank named, as the proper pivot, and changed occasionally. It is used when a column of march (to follow the windings of its route) changes its direction in general less than a quarter circle.

I. Position of the Soldier. When the firelock is given, and is shouldered, the person of the soldier remains in the position described in section I. of the drill without arms, except that the right of the left hand is turned out, the better to embrace the butt; the thumb alone is to appear in front, the four fingers to be under the butt, and the left elbow a little bent inwards, without being separated from the body, or being more backward or forward than the right one. The firelock is placed in the hand, not on the middle of
of the fingers, and so carried, that it shall not rise, advance, or keep back, one should more than the other. The butt must therefore be forward, and as low as can be permitted without reobra; the fore-part nearly even with that of the thigh, and the hind-part of it pressed by the wrist against the thigh. The piece must be kept steady and firm before the hollow of the shoulder. Should the firelock be drawn back, or attempted to be carried high, in that case, one should be advanced, the other kept back, and the upper part of the body doubled, and not placed square with respect to the limbs. Each recruit must be separately taught the position of shoulder-red arms, and not allowed to proceed until he has acquired it.

II. Motion of the Firelock. The following motions of the firelock will be taught and practiced, until each recruit is perfect in them; being necessary for the ease of the folder in the course of exercise: 1. Supporting arms; 2. Carrying arms; 3. Ordering at eased arms; 4. Standing at ease; 5. Attention; 6. Shouldering; 7. Trailing arms; 8. Shouldering from the trail. The recruit must be accustomed to carry his arms for a considerable time together: it is most essential he should do so, and not be allowed to support them so often as is practiced; under the idea that long carrying them is a portion of too much restraint.

III. Forming the Squad. When the squad, or division, of six or eight files, is ordered to Fall in, each man, with carried arms, will, as quick as possible, take his place in the ranks, beginning from the flank to which he is ordered to form. He will draw himself in line by the rule already given, assume the ordered position of a folder, and stand perfectly still and steady, until ordered to stand at ease, or that some other command be given him. Attention must be paid, that the files are correctly close; that the men in the rear ranks cover well, locking their file leaders in the middle of the neck; that the ranks have their proper dilatation of one pace, or 30 inches, from each other; that all the ranks are equally well drilled; that the men do not turn their heads to the right or left; and that each man has the proper unconstrained attitude of a folder.

IV. Open Order. The recruits being formed in three ranks, at close order, on the caution Rear ranks take open order, the flank men, on the right and left of the centre and rear ranks, liep briskly back, one and two paces respectively, face to the right, and stand covered, to mark the ground on which each rank is to halt, and drill at open order: every other individual remains ready to move. On the word March, the drillers front, and the centre and rear ranks fall back one and two paces, each drilling by the right, the instant it takes its ground.

V. Close Order. On the word Rear ranks take close order, the whole remain perfectly steady. At the word March, the ranks close within one pace, marching one and two paces, and then halting.

VI. The Manual Exercise. The following is the regulation for performing the manual exercise, the recruit standing at the position already described, with his firelock shouldered. The manual is not to be executed by one word, or signal, but each separate word of command is to be loudly and distinctly given by the officer who commands the body performing it. Three seconds are the time allotted between each motion, except that of fixed bayonets, in which a longer time must be given.

Order Arms. Bring the firelock to the trail in two motions; seizing it at the flit at the lower loop, just above the flivell; at the second, bring it down to the right side, the butt within two inches of the ground; at the third, drop the butt on the ground, placing the muzzle against the hollow of the right shoulder, and the hand flat upon the fling.

Fix Bayonets. At the word, fix, place the thumb of the right hand, as quick as possible, behind the barrel, taking a grease of the firelock. As soon as the word of command is fully out, pull the firelock a little forward, at the same time drawing out the bayonet with the left hand, and fixing it with the utmost celerity. The instant this is done, return, as quick as possible to the order as above described, and hand perfectly steady.

Shoulder Arms. As soon as the word shoulder is given, take a grieve of the firelock with the right hand, as fixing bayonets; and at the word, arms, the firelock must be thrown with the right hand, in one motion, and with as little appearance of effort as possible, into its proper position on the left shoulder. The hand crosses the body in doing; but must be instantly withdrawn.

Present Arms. First, fixe the firelock with the right hand, beneath the guard, turning the lock to the front, but without moving it from the shoulder; second, bring it to the poise, seizing it with the left hand, the fingers extended along the fling, the wrist upon the guard, and the point of the left thumb equal in height with the eyes; third, bring down the firelock, with a quick motion, as low as the right hand will admit without constraint, drawing back the right foot at the same instant, so that the hollow of it may touch the left heel. The firelock in this position is to be totally supported in the left hand, the body to rest entirely on the left foot, both knees to be straight.

Shoulder Arms. First, by a turn of the wrist, bring the firelock to its proper position on the shoulder, as described above, the left hand grasping the butt; second, quit the right hand, and bring it briskly down to its place at the side.

Charge Bayonets. First, at one motion throw the firelock from the shoulder across the body, to a low diagonal recovery, a position generally denominated porting arms, or preparing for the charge, in which the lock is to be turned to the front, and on the height of the breast, the muzzle fleeting upwards, so that the barrel may cross opposite the point of the left shoulder, with the butt proportionally depressed. The right hand grasps the small of the butt, and the left holds the piece at the flivell, close to the lower pipe, the thumbs of both hands pointing towards the muzzle; second, make a half face to the right, and bring down the firelock to nearly a horizontal position, with the muzzle inclining a little upwards, and the right wrist reining against the hollow of the thigh, just below the hip. N. B. The first motion of the charge is the position which the folder will, either from the shoulder, or after bring, take, in order to advance on an enemy whom it is intended to attack with bayonets fixed. The word of command, for that purpose, is, Prepare to charge. The second position is that which the front rank takes when arrived at a few yards distance only from the body to be attacked. The third motion of the charge is also that which station is are to take, when challenging any person who approaches their poinets.

Shoulder Arms. First, face to the front, and throw up the piece into its position on the shoulder, by a turn of the right wrist, instantly grasping the butt, as above described, with the left hand; second, quit the firelock briskly with the right hand, bringing it to its proper place by the side.

The men must likewise be taught to support arms at three motions, throwing the first and second nearly into one. First, they seize the small of the butt under the locks with the right hand, bringing the butt in front of the groin, and keeping the lock somewhat turned out; second, they bring their left arm under
under the cock; third, they quit the right hand. In carrying arms, from the support, the motions are exactly reversed. In marching any distance, or in standing at a齐 when supporting, the men are allowed to bring their right hand across the body, to the small of the butt, which latter must, in that case, be thrown still more forward; the fingers of the left hand being uppermost, must be placed between the body and the right elbow. The right hands are to be instantly removed, when the division halts, or is ordered to dress by the right. In regard to the motions of setting, grounding, and trailing, as well as piling arms, it will be sufficient for the followers to be taught to perform them in the quitted and most convenient method. Unfixing bayonets is to be done from the order, in the same manner as fixing them.

Sentries posted with shouldered arms, are permitted afterwards to support, but not to flounce them. On the approach of an officer, they immediately carry their arms, and put themselves into the proper position; not at the instant he passes, but by the time he is within twenty yards of their poll, so that they may be perfectly ready before he comes up. If a field officer, he is entitled to the present arms. Corporals marching with relics, or commanding detachments or divisions, will carry their arms advanced.

VII. The Platoon Exercise. When perfect in the manual, the troops are next to be taught this part of their duties, and the manner in which to execute the several evolutions. The correct flanding at shouldered arms, the first word given is:

*Make Ready. This is done by bringing the firelock to the recover, and instantaneously cocking.*

**Present.** Slip the left hand along the fling as far as the swell of the firelock, and bring the piece down to the present, stepping back about six inches to the rear with the right foot.

**Fire.** Having fired, drop the firelock briskly to the priming position, and half cock.

**Handle Cartridge.** First, draw the cartridge from the pocket; second, bring it to the mouth, holding it between the forefinger and thumb, and bite away the top of it.

**Prime.** First, make a little powder into the pan; second, fling the pan with the three left fingers; third, seize the small of the butt with the same three fingers.

**Load.** First, face to the left on both heels, so that the right toe may point directly to the front, and the body be a very little faced to the left, bringing, at the same time, the firelock round to the left side, without linking it. It should, while in this position, be nearly perpendicular (having the muzzle only a small degree brought forward); and, as soon as it is Ready there, it must instantly be forced down within two inches of the ground, the butt nearly opposite to the left heel, and the firelock itself somewhat sloped, and directly to the front. The right hand at the same instant catches the muzzle in order to steady it; second, fling the powder into the barrel, putting it in after the paper and ball; third, seize the top of the ramrod with the fore-finger and thumb.

**Draw Ram-rods.** First, force the ram-rod half out, and seize it, back-handed, exactly in the middle; second, draw it entirely out, and turning it with the whole hand and arm extended from you, put it one inch into the barrel.

**Ram down Cartridge.** First, pull the ram-rod down, holding it as before, exactly in the middle, till the hand touches the muzzle; second, fling the fore-finger and thumb to the upper end, without letting the ram-rod fall further into the barrel; third, pull the cartridge well down to the bottom; fourth, strike it two very quick strokes with the ram-rod.

**Return Ram-rod.** First, draw the ram-rod half out, catching it back-handed; second, draw it totally out, turning it very briskly from you, with the arm extended, and put it into the loops, forcing it as quick as possible to the bottom; then face to the proper front, the finger and thumb of the right hand holding the ram-rod, as in the position immediately previous to drawing it, and the butt raised two inches from the ground.

**Shoulder Arms.** Strike the top of the muzzle smartly with the right hand, to fix the bayonet and ram-rod more firmly, and at the same time throw it firmly up at the proper motion to the shoulder. N.B. Though the butts are not come to the ground in calling about, as accidents may happen from it, yet they are permitted, while loading, to be loosed; but it must be done without noise, and in a manner imperceptible in the front.

In priming and loading quick, 1st, bring the firelock down in one brisk motion to the priming position. The thumb of the right hand placed against the pan cover or steel, the fingers clenched, and the elbow a little turned out, so that the wrist may be clear of the cock. 2d. Open and advance the pan by throwing up the drill with a strong motion of the right arm, turning the elbow in, and keeping the firelock steady in the left hand. 3d. Bring your hand round to the pouch, and draw out the cartridge. The rest as above described; except that in the quick loading, all the motions are to be done with the utmost dispatch possible, the folders taking their time from the finger-man in front, for calling about and shuffling only.

In firing three deep, the priming position for the front rank is the height of the waistband of the breeches; for the centre rank, about the middle of the stomach; and for the rear rank, close to the breast. The firelock in all these positions is to be kept perfectly horizontal.

**As Front Rank kneeling—make ready.** Bring the firelock briskly up to the recover, catching it in the left hand, and, without stopping, sink down with a quick motion on the right knee, keeping the left foot fast, the butt of the firelock at the same moment falling upon the ground. Then cock, and instantly seize the cock and feel together in the right hand, holding the piece firm in the left, about the middle of that part which is between the cock and the swell of the drill; the point of the left thumb to be close to the swell, and pointing upwards. As the body is linking, the right knee is to be thrown so far back, that the left leg may be right up and down, the right foot a little turned out, body stiff, and the head as much up as if shouldered. The firelock must be upright, the butt about four inches to the right of the insole of the left foot.

**Present.** Bring the firelock down firmly to the present, by sliding the left hand to the full extent of the arm along the fling, without letting the motion tell; the right hand at the same time springing up the butt by the cock so high against the right shoulder, that the head may not be too much lowered in taking aim; the right check to be close to the butt, the left eye flat, and the middle finger of the right hand on the trigger. Look along the barrel with the right eye, from the breech-pin to the muzzle, and remain steady.

**Fire.** Pull the trigger strong with the middle finger, and, as soon as fired, springing up nimblly upon the left leg, keeping the body erect, and the left foot fast, and bringing the right heel to the hollow of the left. At the same instant, drop the firelock to the priming position, half cock, handle cartridge, and go on with the loading motions as before described.

**As Centre Rank—make ready.** Springing briskly to the recover. As soon as the left hand seizes it above the lock, raise the right elbow a little, placing the thumb of that hand upon the cock, with the fingers open on the plate of the
the lock, and then, as quick as possible, cock the piece, by dropping the elbow, and forcing down the cock with the thumb. Step at the same time with the right foot a moderate pace to the right, and keeping the left foot, feize the small of the butt with the right hand. The piece must be held in this position perpendicular, and oppose the left side of the face, the butt close to the break, but not prefixed, the butt forward and fall to the front, and the head erect.

Prefet, as in the foregoing explanation.

Firr. Pull the trigger strong with the middle finger; and, as soon as fired, bring the firelock to the proper position. And load as before, with this difference only, that the left foot is to be drawn up to the right, at the same time that the firelock is brought down to the proper position; and that, immediately after the firelock is thrown up to the shoulder, the men spring to the left again, and cover their file leaders.

As Rear Rank—make ready. Recover and cock as before directed for the centre rank. As the firelock is brought to the receiver, it is briskly to the right a full pace, at the same time placing the left heel about six inches before the point of the right foot. The body to be kept straight, and the firelock to be brought as near to the face as possible.

Prefet, as in the foregoing explanation.

Firr. as before; remembering only the difference of the proper position for this rank. After firing and recovering the shoulder, the men file as the centre rank does.

In filing with the front rank filing, that rank makes ready, &c. as mentioned in the first part of the platoon exercise. The platoon exercise is always to be performed with ranks closed, except at the drill.

VIII. Firings. When the recruits have acquired the management of their arms, and are perfect in the motions of the manual and platoon exercises, they will be instructed in closed ranks, at firing, viz. direct to their front; 2dly, obliquely to the right and left; and, 3dly, by files.

IX. Marching to the front and rear. The division, or squad, is to be particularly well drilled, files correct, arms carried, the rear ranks covering exactly, and each individual to have his full attitude and position, before the squad is ordered to move. The march will be made by the right or left flank, and a proper trained man will therefore conduct it. The word division may be given as a caution; and at the word march, each man files forward a full pace. The recruit must not turn his head to the hand to which he is drilling, as a turning of the shoulders would undoubtedly follow. His elbows must be kept Ready, without constraint: if they are opened from his body, the next man must be pressed upon; if they are closed, there arises an improper distance, which must be filled up. In either case, waving on the march will take place, and is therefore to be avoided. The going to the right or left about, in march, is not to be at drill practised; but the squad is to halt, front by command, and then march. As the being able to march straight forward is of the utmost consequence, the officer commanding the drill will take every pains to perfect his squad in it. For this purpose he will often go to the rear, pace himself behind the flank file which regulates the march, and take a point or object exactly in front of that file. He will then command, march; and remaining in his place, will direct the advance of the squad. By keeping the flank file always in a line with the object. It is also from behind he will soon perceive the leaning back of a shoulder, or the bringing it forward: faults which ought instantly to be rectified, as productive of the worst consequence in a line, where one man, by bringing forward a shoulder, may change the direction of the march, and oblige the wing of a battalion to run, in order to keep drilled. In short, it is impossible to labour too much at making the soldier march straightforward, keeping always the same front as when he flipped off. This is effected by moving solely from the command, keeping the body steady, the shoulders square, and the head well without difficulty be at tained, on a strict attention to the rules for marching, and a careful observance of an equal length of step, and an equal cadence or time of march.

Changing from ordinary to quick time, and from quick to ordinary, must always be preceded by a halt. Although this may not appear essential for the movements of a division or battalion, it is absolutely so for those of a larger body, and is therefore required in small ones. Turning on the march, in order to continue it, though inaccurate and improper for a large body, is necessary, and must often be allowed, in the movements of small divisions in file or front, when connected with others in line or column. As helps for fixing the true cadence of the march, the plume must often be referred to. The words left, right, may when necessary, be repeated; flaws for ordinary, and more rapidly for quick time. Strong taps of the drum, regulated by the plume, may be allowed to be given immediately before the word march, to imprint the required measure on the mind of the recruit; but they are on no account, or in any situation, to be given during the march.

X. Open and close Order, on March. The squad, when moving to the front in ordinary time, receives the word, Rear ranks take open order; on which the front rank continues its march without altering the pace, and the centre and rear ranks mark the time, viz. the centre once, and flaps off at the second pace; the rear rank moving forward on the third. On the word Rear ranks take close order, the centre and rear ranks flaps numbly up to close order, and instantly resume the pace at which the first rank has continued to march.

XL March in File to a Flank. The accuracy of the march in file is of essential in all deployments into line, and in the internal movements of the divisions of the battalion, that the flank cannot be too much exercised to it. The whole battalion, as well as its divisions, is required to make this flank movement, without the least opening out, or lengthening of the file, and in perfect cadence and equality of step. After facing, and at the word march, the whole squad files off at the same instant, each replacing, or rather overlapping the foot of the man before him, i.e. the right foot of the second man comes within the left foot of the first, and thus of every one; more or less overlapping, according to the closeness or openness of the files, and the length of step. The front rank will march straight along the given line, each folder of that rank looking along the necks of those before him; over to the right or left; otherwise a waving of the march will take place, and of course the lufs and extension of line and distance, whenever the body returns to its proper front. The centre and rear ranks must look to, and regulate themselves by their leaders of the front rank, and always drill in their file. Although file marching is generally in quick, yet it must also be practised in ordinary time. The lower portion of feet takes place in all marching in front, where the ranks are close and locked up. With a little attention and practice, this mode of marching, apparently so difficult, will be found by every soldier to be easier than the common method of marching by files, when, on every halt, the rear must run up to gain the ground it has unnecessarily lost.

XII. Marching in File. The squad, when marching in file, must be accustomed to wheel its head to either flank; each
each file following in succession, without losing or increasing distance. On this occasion, each file makes its separate wheel, on a pivot moveable in a very small degree, but without altering its time of march, or the eyes of the rear ranks being turned from their front rank. The front rank men, whether pivot-men or not, must keep to their distance; and the wheeling men must take a very extended step, and lose no time in moving on.

XIII. Oblique Marching in Front. When the squad is marching in front, and receives the word to the right oblique, each man, in his line, as his right foot rises, will, instead of throwing it straight forward, carry it to the diagonal direction, as has been already explained in § 8. of the drill without arms, taking care not to alter the position of his body, head or head. The greatest attention is to be paid to the shoulders of every man in the squad, that they remain parallel to the line on which they first were placed, and that the right shoulders do not fall to the rear, which they are very apt to do in obliqueing to the right, and which immediately changes the direction of the front. On the word forward, the incline eases, and the whole march forward. In obliqueing to the left, the same rules are to be observed, with the difference of the left leg going to the left, and attention to keeping up the left shoulder. The time instructions that are given for ordinary time, serve also for quick time; but this movement, though it may be made by a small division, cannot be required from a larger body. Obliqueing to the right is sometimes to be practiced with eyes to the left, and obliqueing to the left, with eyes to the right; as being absolutely necessary on many occasions: for if one of the battalions of a line in advancing be ordered to oblique to the right or to the left, the eyes must still continue turned towards its centre.

XIV. Oblique Marching in File. In obliqueing to the right or left by files, the centre and rear rank men will continue looking to their leaders of the front rank. Each file is to consider itself as a rank entire, and is to preserve the same front, and position of the shoulders, during the oblique, as before it began. This being a very useful movement, recruits are to be often practiced in it.

XV. Wheeling forward from the Halts. The directions already given for the wheeling of a single rank, are to be strictly attended to in this wheel of the squad. On the word right, or left wheel, the rear ranks, if at one pace distance,轮 up. At the word march, the whole file together in the quickest time, and the rear ranks, during the wheel, incline so as to cover their proper front rank men. At the word halt, the whole remain perfectly steady.

XVI. Wheeling backward. The squad must be much practiced in wheeling backward in the quickest time. In this wheel the rear ranks may preserve their distance of one pace from each other. Great attention should be paid to prevent the recruits from closing their eyes on the ground.

XVII. Wheeling from the March. The directions for wheeling on at halt and on a moveable pivot, have already been given under the drill without arms. The squad should now be practiced in both, until thoroughly confirmed in those movements.

XVIII. Stepping out, etc. The squad must likewise be practiced in stepping out, stepping short, marking time, changing the feet, the sole step, and stepping back; the instructions for which have been fully detailed in the first part of the drill.

It can neither be too strongly inculcated, nor too often remembered, that upon the correct equality of march, established and practised by all the troops of the same army, every just movement and manoeuvre depend. If this is not attended to, diffusion and confusion will necessarily take place on the junction of several battalions in corps; although, taken individually, each may be in its drill fitly and well trained. It is in the original instruction of the recruit and squad, that this great point is to be laboured at and attended. The time and length of step, on all occasions, are prescribed. The time is intantly altered by the frequent corrections of the plumelet, which, when supplied, will from time to time give each man that habitual measure to which he is accustomed. Every drill must therefore have it at hand; and, as already observed, before any squad or larger body is put in march, five or six long taps of the drum may be given, in exact time, as regulated by the plumelet, which will imprint the true measure on each car, and prepare for taking an accurate step at the word march. The length of step is only to be acquired by repeated trial; and therefore, before the recruit is put in motion, each instructor should ascertain the space on which he is to drill his men; he will therefore (supposing that he himself is accurate in his pace, and that there is ground for that purpose) mark out an oblong square of sixty paces by twenty or thirty, the corners of which will be established by halberts, flones, or any other visible manner. Along the sides of this figure he will march the pivot flank of his squad, making correct wheels and halts at the angles. The time of march being exactly ascertained, he will then see that the sides of the oblong are gone over at the known number of steps; and if there be any inaccuracy, he will caution or shorten the step, till the squad marches with the utmost precision, every man preserving his just position, and all the other indispensable attentions in marching being strictly observed. Where there is a sufficiency of ground, the squads will occasionally march over larger spaces: but the distances should in the same manner be exactly determined, so that there may be no doubt as to the true length of the step. In proportion to the length of squads or drills, one or more must be led in to keep company each, to march on the flank, give distances, and in other points regulate the motions of the drill.

Formation and Exercise of the Platoon, or Company. The recruit being thorough grounded in all the preceeding parts of the drill, he now is to be instructed in the movements of the platoon, as a more immediate preparation for his joining the battalion. For this purpose, from ten to twenty files are to be assembled, formed, and told off in the following manner, as company in the battalion.

I. The platoon falls in three ranks, in close order, with shouldered arms; the files lightly touching, but without crowding. Each man will then occupy a space of about 22 inches. The commander of the platoon takes post on the right of the front rank, covered by a sergeant in the rear rank. The other sergeants will form a fourth, or perpendicular rank, three paces from the rear rank. The platoon will be told off into sub-divisions, and, if of sufficient length, into four sections; but as a section should never be less than five files, it will often happen that, for the purposes of march, three sections only can be formed. The four best-trained soldiers are to be placed in the front rank, on the right and left of each subdivision. When thus formed, the platoon will be practiced in opening and closing of ranks; dehiscing to the front, to the rear, or in an oblique direction, by the right or left; and exercised in the several motions of the firelock. Close order is the chief and ordinary order in which the battalion and its parts at all times affile and form. Open order is only regarded as an exception from it, and occasionally used in situations of parade and review. In close order, the rear ranks are closed up to within one pace; the length of which is to be taken from the
the heels of one rank to those of the next. At open order they are two paces distant from each other.

11. Marching to the Front. In the drill of the platoon, the person instructing must always consider it as a company in battalions, and regulate all movements upon that principle. He will therefore, before he puts it in motion to front or rear, indicate which flank is to direct, by giving the word Eyes Right, or Eyes Left, and then March. Should the right be the directing flank, the commander of the platoon himself will fix on objects to march upon, in a line truly perpendicular to the front of his corps. When the left flank is ordered to direct, he and his covering sergeant will shift to the left of the front rank, and take such objects to march upon. To march on one object only, and to prefer a straight line, it is an operation not to be depended upon. The commander of the platoon therefore, before the word to march is given, will endeavour to remark some distinct object on the ground in his own front, and perpendicular to the directing flank. He will then observe some nearer and intermediate point in the same line, such as a stone, tuft of grass, &c. These he will move upon with accuracy; and as he approaches the nearest of those points, he must from time to time choose fresh ones, in the original direction, which he will by this means prefer, never having fewer than two such points to move upon. If no object in the true line can be ascertained, his own squares or parts of persons must determine the direction of the march. A person placed in the rear of a body can, more readily than if posted in its front, determine the line which is perpendicular to that front; and, could we suppose ranks and files perfectly correct, the prolongation of each file would be a perpendicular to the front of the body. As the march of every corps, except in the case of inclining, is made on lines perpendicular to its then front, each individual composing that corps, must in his person be placed and remain perfectly square to the given line; otherwise he will naturally and inevitably move in a direction perpendicular to his own person, and thereby open out or close in according to the manner in which he is turned from the true point of his march. If the distortion of a single file (and all turnings of the head do dislodge) operates in this manner, it may easily be imagined what that of several will occasion, each of whom is marching on a different front, and whose lines of direction are crossing each other. Accuracy and squares is position, the equality of cadence and file, the light touch of the files which is never to be relinquished, just distances, and true lines of movement, will give, without apparent constraint, the head being turned, or the lead trouble taken in dressing, the most decisive exactness in the marches and operations of the largest bodies.

The platoon, during its march in line, will occasionally be ordered to step out, mark time, open and close ranks, and oblique, as already described.

111. Side Step. The side or closing step must also be frequently practised. It is very necessary and useful on many occasions, when halted, and when a very small distance is to be moved to either flank; for instance to open or close files; to join one division to, or open it from, another; to regain an interval in line; to move a whole battalion or parade twenty or thirty paces to a flank; to regulate distances between close co umns, before deploying, &c. Alterations made in this manner are imperceptible from the front, and better made than by facing and file-marching. The words of command must be decided and strong. When the whole platoon is to close; at the word, to Right—Close, the platoon officer takes one step to the front, and instantly faces about, the covering sergeant replacing him. On the word March, the whole more together. On the Halt, the platoon officer resumes his place, having leaped in the same manner as the men, but fronting them, and thereby affixed in their view the direction of the division.

IV. Quick Step. The platoon must be accustomed, at the halt on the words Back Step—March, to leap back any ordered number of paces in the ordinary time and length, as it is an operation that may be sometimes required from a battalion.

V. File Marching. In marching by files, the commander of the platoon may lead the front rank. If therefore the movement is by the left, on the word to the Left—Face, he and his covering sergeant will instantly shift to the left flank of the division. At the word Quick—March, the whole files off together; and on the Halt, Front, the leader and his sergeant will return to their posts on the right.

VI. Wheeling from a Halt. In wheeling, whether forward or backward, from a halt, the commander of the platoon, on the word Right or Left Wheel, moves out, and places himself one pace in front of the centre of his platoon. During the wheel, he turns towards his men, and inclines towards that flank which has been named as the directing or pivot one; giving the word Halt—Dress, when his wheeling man has just completed the required degree of wheel. He then squares his platoon, but without moving what was the flanking flank, and takes his post on the now directing flank.

VII. Wheeling forward by Subdivisions from Line. On the word By Subdivisions—to the Right, Wheel, the commander of the platoon places himself one pace in front of the centre of the right subdivision; at the same time, the men on the right of the front rank of each subdivision face to the right. At the word March, each subdivision files off in wheeling time, observing the directions above given for wheeling forward. The commander of the platoon, turning towards the men of the leading subdivision, and inclining to its left (the proper pivot flank), gives the word Halt—Dress, for both subdivisions, as his wheeling man is taking the last step that finishes the wheel square; and instantly posts himself on the left, the pivot flank. The covering sergeant, during the wheel, goes round by the rear, and takes post on the pivot flank of the second subdivision. It is to be observed, that the commander of the platoon invariably takes post with the leading subdivision; therefore, when the platoon wheels by subdivisions to the left, the commander of the platoon moves out to the centre of the left subdivision, and during the wheel, inclines towards the right, row become the proper pivot flanks of the subdivisions. The proper pivot flank in column, is that which, when wheeled up to, preserves the divisions of the line in the natural order, and to their proper front; the other is denominated the reverse flank. In column, divisions cover and dres to the proper pivot flank; to the left when the right is in front, and to the right when the left is in front.

VIII. Wheeling backward by Subdivisions from Line. The platoon will also break into open column of subdivisions by wheeling backwards. When the right is intended to be in front; at the word, By Subdivisions, on your left backwards Wheel, the commander of the platoon moves out briskly, and places himself in front of the centre of the right subdivision; the man on the left of the front rank of each subdivision at the same time faces to the right. On the word March, each subdivision wheels backward in quickstep time. During the wheel, the commander of the platoon turns towards his men, inclining at the same time to the left, or pivot flank; and on completing the wheel, gives the word Halt—Dress, to both divisions. He and his covering
covering sergeant then place themselves on the left flanks of their subdivisions. It may be considered as a rule almost general (the reasons for which are subsequently given), that all wheels of the battalion or line (when halted, and when the divisions do not exceed sixteen or eighteen files) into column, should be backward; and all wheels from column into line, forward. The only necessary exceptions seem to be in narrow ground where there is not room for such wheels.

IX. Marching on an Alignment, in open Column of Subdivisions. The platoon having wheeled backwards by subdivisions from line, as just stated, and a distinct marked object in the prolongation of the two pivot flanks being taken, the commander of the platoon, who is now on the pivot flank of the leading subdivision, immediately fixes on his intermediate points to march on. On the word March, both subdivisions step off at the same instant; the leader of the foremost corps marching with the utmost readiness and equality of pace on the points he has taken; and the commander of the second division preserving the leader of the first in an exact line with the distant object, at the same time he keeps the distance necessary for forming from the preceding division, which distance is to be taken from the front rank. These objects are in themselves sufficient to occupy the whole attention of the leaders of the two divisions; therefore they must not look to, nor endeavour to correct, the march of their men, which care must be entirely left to the non-commissioned officers of the supernumerary rank.

X. Wheeling into Line from open Column of Subdivisions. The platoon being in open column of subdivisions, marching at the ordinary step on the alignment, receives the word Halt from the instructor of the drill. Both subdivisions instantly halt, and the instructor fees that the leaders of the divisions are correct on the line in which they have moved. He then gives the word (supposing the right of the platoon to be in front), By Subdivisions, to the left wheel into Line. On this the commander of the platoon goes to the centre of his subdivision; the two pivot men face to their left, exactly square with the alignment, and a sergeant runs out and places himself in a line with them, so as to mark the precise point at which the right flank of the leading subdivision is to halt, when it shall have completed its wheel. At the word March, the whole wheel up in quickest time. During the wheel, the whole platoon remains under the direction of the commander, who inclines to the wheeling flank, and gives the word Halt—Drifts, the moment the wheel of the division is completing. He also, if necessary, corrects the internal drizzling of the platoon on the sergeant and pivot-men. This drizzling must be quickly made; and when done, the commander of the platoon gives the word Eyes Front, in a moderate tone of voice, and resumes his poll in line. In all wheels of the divisions of a column (either from the halt or from the march) that are made on a halted pivot, the flank firelock of the front rank on the hand wheeled to, is such pivot; not the officer who may be on that flank, and whose business is to conform to it. All wheels by subdivisions or columns from line into column, or from column into line, are performed on the word given by the commander of a battalion, when the whole of a battalion is at the same instant to wheel; or on the word given by the captain of the company, when companies singly, or successively, so wheel. They are not to be repeated by the leaders of its divisions.

XI. In Open Column of Subdivisions, wheeling into a new Direction on a moveable Pivot. The commander of the leading subdivision, when at a due distance from the intended new direction, will give the word Right or Left Shoulders Forward; and he himself carefully preferring the rate of march, without the least alteration of step or time, will begin to circle in his own person from the end into the new direction, so as not to make an abrupt wheel, or that other flank shall be stationary. The rear of his division, on the principle of drifting, will conform to the direction he is giving them; when this is effected, he will give the word Forward. The leader of the second subdivision, when he arrives at the ground on which the first began to wheel, will in this manner follow the exact tract of the first, always preferring his proper distance from him. Thus, without the constraint of formal wheels, a column, when not confined to its flanks, may be conducted in all kinds of winding and changeable directions: for, if the changes be made gradual and circling, and that the pivot leaders of subdivisions...
Battalion.

divisions pursue their proper path, at the same uniform equal pace, the true distances will be preferred, which is the great regulation object on this occasion, and to which every other must give way.

XIII. Countermarch by Files. The platoon, when it is to countermarch, must always be considered as a division of a battalion in column. The instructor of the drill will therefore, previous to giving the command to countermarch, signify whether the right or left is supposed to be in front, that the commander of the platoon and his covering sergeant may be placed on the pivot flank, before such command is given; as it is an invariable rule in the countermarch of the divisions of a column by files, that the facing he made from the flank, then the pivot one, to the one which is to become front. On the word To the Right or Left Face, the platoon faces; the commander of it immediately goes to the other flank; and his covering sergeant, advancing to the front which he has quitted, faces to the right about. At the word Quick March, the whole, except the sergeant coverer, files off together: the platoon officer wheeling short round the rear rank (viz. to his right, if he has fluted to the right of the platoon, or to his left, if he remains on the left of it); and proceeds, followed by the platoon in file, till he has conducted his pivot from one rank man close to his sergeant, who has remained immovable. He then gives the words Halt — Front — Drills; squares, and closes his platoon on his sergeant, and then replaces him. All countermarches by files necessarily tend to an extension of the files. Unity of step is therefore absolutely indispensible, and the greatest care must be taken, that the wheel of each file be made close, quick, and at an increased length of step of the wheeling man, so as not to retard or lengthen out the march of the whole.

XIV. Wheeling on the Centre of the Platoon. The platoon must be accustomed to wheel upon its centre, half backward, half forward, and to be liable into every shape which circumstances can require of it; but always in order, and by a decided command. The words of command are, Platoon — to your Centre, to the Right Wheel, to the Left Wheel; to the Right about wheel; &c. When the wheel is to be made to the right, or right about, the right half platoon is the one to wheel backward, and the left forward. The reverse will take place when the wheel is to be made to the left, or to the left about. On the word March, the whole move together in the quickest time, regulating by the two flank men, who, during the wheel, preserve themselves in a line with the centre of the platoon. As soon as the required degree of wheel is performed, the commander of the platoon gives the word Halt — Drills, and instantly squares it from that flank on which he himself is to take post.

XV. Oblique Marching. The instructor of the drill will have the oblique march frequently practised in platoon, in subdivisions, and in file. He will make it, when in divisions, that the rear ranks look well up, and cover exactly; when in file, that the exact distances are preferred between the files; and in both cases, that the platoon, during its march, continues parallel to the position from which it commenced obliquing.

XVI. Increasing and diminishing the Front of an Open Column on the March. 1. Increasing: The platoon marching at the ordinary time in open column of subdivisions (supposing the right in front), receives from the instructor of the drill the cautionary command Form Platoon. The commander of the platoon instantly gives the word Left oblique — Quick March, on which the rear subdivision oblique to the left, and as soon as its right flank is open, receives the word Forward. When it gets up to the first subdivision, which has continued to march with the utmost steadiness at the ordinary pace, the commander of the platoon gives the word Halt — March, and takes post on the pivot flank. 2. Diminishing: When the instructor of the drill gives the caution to form subdivisions, the commander of the platoon immediately orders, Left Subdivision; Mark Time. This it does till the right one, which continues its march readily at the ordinary pace, has cleared its flank. He then orders the left subdivision, Quick oblique; and when he perceives that it has doubled properly behind the right one, he gives the word Forward, on which it takes up the ordinary march, and follows at its due distance. The same directions that apply to increasing or diminishing by subdivisions, apply equally to increasing or diminishing by file, which individually repeat the same operations. The words for the subdivisions or sections increasing or diminishing the front of a column, are given by the commander of a company, and not repeated by those of its divisions. Increasing and reducing the front of a column is an operation that will frequently occur in the march of large bodies: and it is of the utmost importance that it be performed with exactness. The instructor of the drill must therefore be particularly attentive, that the transition from one situation to the other be made as quick as possible; that the leading division continues its march at the regular time and length of pace; and that the exact distances between the divisions be accurately preserved. During the operation, the ranks must be well closed; arms carried, and the greatest attention required from each individual.

XVIII. The
BATTALION.

XVIII. The Platoon in open Column of Subdivisions to pass a short Defile by breaking off Files. We suppose the platoon in open column of subdivisions, with the right in front, marching in ordinary time. When the leading division is arrived within a few paces of the defile, it receives from the instructor of the drill an order to break off a certain number of the files (suppose three); the commander of the leading division instantly gives the words, Three Files on the Left, Right turn. The named files immediately turn to their right, and wheel out in rear of the three adjoining files. The commander of the subdivision himself closes the flank of the part formed. When the second subdivision comes to the spot where the first division contracted its front, it will receive the same words of command from its own leader, and will proceed in like manner. Should it be required to diminish the front of the column one or two files more, the commander of the leading division will, as before, order the desired number of files to turn; on which those already in the rear will incline to their right, so as to cover the files now ordered to break off, and which are wheeling out in the manner already prescribed. In this movement, the files in the rear of the subdivisions must look well up, so as not to impede the march of the preceding division. At the defile widens, or the instructor of the drill shall direct, the commander of the leading subdivision will order files to move up to the front, by giving the word One, two, or three Files to the Front; on which the named files turn to their front, the left, and lengthening their pace, march up, file by file, to the front of their subdivision, and immediately resume the ordinary pace. Those files which are to continue in the rear, will oblique to the left, lengthening also their step, till they cover, and are closed up to the three files on the left flank of their subdivision.

XIX. Marching in quick Time. The platoon must frequently be practiced to march in quick time, particularly in file, until the men have acquired the utmost precision in this movement, which is essential in all deployments from close column. The platoon will also occasionally be marched in front at the same step, as it may be sometimes required from small bodies.

XX. Forming to the Front from File. The platoon, when marching in file, may form to its front, either in sections, subdivisions, or in platoon. The right flank being supposed to lead, on the word halt, front, the platoon instantly halts, and faces to its left. The word is then given, by sections, subdivisions, or platoon, on your left backwards wheel; and at the word march, the wheel ordered is performed in the manner already directed in sect. xvii. But in situations where it may have been necessary to order an extension of files (such as will sometimes occur in marching through the streets of a town), a body thus moving, in order to avoid incorrect distances between the divisions, may form to the front in the following manner, either by platoon, subdivisions, or sections. On the word to the front form platoon, the front rank man of the leading file halts alone, and is instantly covered by his centre and rear rank men. Every other file of the platoon makes a half face to the left, and successively moving up, drefs on the right file. When the commander of the platoon feels it is properly dresed, he gives the word eyes left, and places himself on the pivot flank. Should the order have been, to the front form sections or subdivisions, the leading subdivision or section will proceed in the manner already detailed for the platoon. The succeeding subdivisions or sections will each continue moving on, until its front file arrives at the proper forming distance from the division in its front; when it will receive from its commander the word to the front form, and will instantly form up by files in the manner already described.

XXI. Forming from File to either Flank. The platoon marching in file, suppose from the right, has only to halt and front to be formed to the left flank. To form to the right, it will receive the word to the right form. The front rank man of the leading file instantly turns to his right, and halts; his centre and rear rank men move round and cover him. All the other files of the platoon make a half turn to their left, and move round successively in a line with the right hand file; the centre and rear rank men of each file keeping closed well up to their file leaders.

XXII. To form to either Flank from open Column of Subdivisions or Sections. The platoon marching in the ordinary time in open column of subdivisions or sections, to form to its left receives the words halt, left column, and form, march, &c., and proceeds as has already been shown in sect. x. To form the platoon to its right flank, the instructor of the drill gives the cautionary word of command, to the right form platoon; on which the commanders of the several divisions shift to the other flank, and the commander of the leading subdivision or section instantly gives the word to his division, right column; and when it has wheel'd square, he orders halt, right drefs; gores to the right flank of his division, and dreses it on the intended line of formation. The commander of the other subdivisions or sections, on the leading one being ordered to wheel, gives the word to the left column, and gradually inclines so as to be able to march clear of the rear rank of the division forming. This being effected, the word forward will be given to each division, and they move on in the rear of the one formed. When the second subdivision or section is arrived at the left flank of the first, its commander gives the word right wheel, then halt, drefs up; on which the division moves up into the line with the one formed; and its commander instantly places himself two or three files from the left of his first division, and dreses his own on it as quickly and as accurately as possible. Thus each succeeding section should proceed, until the whole be formed.

XXIII. The Platoon moving to the Front to gain Ground to a Flank, by a March in Echelon by Sections. In the drill of the platoon, when the column is completely formed, he may be taught to march in echelon by sections. This is a very useful movement for a battalion or larger body moving in line, that is required to gain ground to a flank, and may be substituted instead of the oblique march. It will be performed in the following manner; the platoon marching to the front in the ordinary time, receives the word by sections to the right. The right hand men of the front rank of each section turning in a small degree to their right, mark the time for three paces, during which the sections are wheeling in ordinary time on their pivot men. At the fourth pace, and at the word forward, the whole move on direct to the front that each section has now acquired, and the commander of each section having taken post on the right of his division, the platoon continues its march in echelon. On the word form platoon, the pivot men mark the time for three paces, turning back in a small degree to the left, their original front; and the sections instantly wheel backward into line. At the fourth pace, the whole move forward. When the platoon is in two ranks only, two paces instead of three will be sufficient to mark time, and to step off at the third instead of the fourth pace.

XXIV. From three Ranks, forming into two. The platoon halted, is ordered form two deep. The rear rank men of the left sub-division instantly step back one pace. On the word left face, the rear rank of each sub-division face.

5 M
BATTALION.

The word *quick march* is then given, on which the men of the rear rank of the left sub-division step short, until those of the right get up to them; they then move on with them in file. As their rear is clearing the left flank of the platoon, the commander, who has shifted to this flank during the movement, gives the word *halt, front, drefs up,* instantly dreses them on the standing part of his platoon, and refumes his post on the right. One third or more sub-division is thus added to the front of the company, which is here suppos'd standing as one in a battalion column.

XXV. *From two Ranks, forming into three.* The platoon being halted, and told off into three sections, it receives the word *form three deep,* on which the third section instantly steps back one pace. The word *right face* is then given, and the man on the right of its front rank, on facing, disengages a little to his right. On the word *quick march,* the front rank men of the third section step off, those of the other mark the time, till they have passed, and then follow. When the leading man has got to the right of the platoon, the commander gives the word *halt front,* on which, each man halts, faces to his left, and instantly covers his proper file leader.

In pursuance of the foregoing instructions, and on the principles they contain, every company of a battalion must be frequently exercised by its own officers, each superintending a rank, or an allotted part of the whole. On a space of seventy or eighty yards square, every circumstance can be practised that is necessary to qualify it for the operations of the battalion. That space being pointed out by under officers, or other marks, as directed at the latter end of the drill with arms, the company will practise, both at open and close files, without and with arms.

By ranks, 1st, March in single file, by successive ranks, along the four sides of the square; the same by twos. 2d, March and wheel by ranks of fours; file off singly and double up, preserving proper distances, and not quickening on the wheel. 3d, March and wheel by sub-divisions of ranks. 4th, March and wheel by whole ranks. 5th, March to front and to rear, ranks at ten paces alreadv. 6th, March the company in a single rank to front and to rear, by a flank and by the centre. 7th, Oblique, by ranks. 8th, Open and close files, and intervals, by the file (rep. 9th, March in file to either flank. 10th, Ranks successively advance fix or eight paces, halt, and drefs ; ranks successively fall back the fame number of paces, halt and dres. 11th, Advance or retire two or three flank men, the ranks dres to them. 12th, Open and close ranks.

At close ranks and files. 13th, March and wheel in all directions, by sub-divisions and by company; shorten filep, and lengthen it; the march to be made both in ordinary and quick time; the wheels to be made in wheeling time. 14th, Advance and retire two or three flank files, and dres to them. 15th, Open and close to the flank by the file (rep. 16th, Change front by the countermarch by files. 17th, March in file to the flanks, close, and without opening out, form to the front, or to either flank. 18th, March oblique. 19th, Sub-divisions double on the march, and again form up by obliquing. 20th, Wheel backwards by sub-divisions, March along the line to prolong it; form to the flank by wheeling up, or to the front by obliquing. 21th, File from the flank of company to the rear, as in the passage of lines; halt front, close into pivot files, wheel up as in forming file. 22d, From three deep, form two deep. 23d, From two deep, form three deep. 24th, Exercise of the firelock, manual and platoon, by ranks and company. 25th, Firings by Files, sub-divisions, and company.

The necessary pauses and formations between these movements in order to connect them, must of course be made. They may be practised in whatever succession that shall at the same time be found proper. The greatest precision must be required and observed in their execution, according to the rules already laid down.

Every officer must be instructed in each individual circumstance required of a recruit, or a folder; also in the exercise of the sword; and accustomed to give words of command with that energy and precision which is to be essential. Every officer, on first joining a regiment, is to be examined by the commanding officer; and if he is found imperfect in the knowledge of the movements required from a folder, he must be ordered to be exercised, that he may learn their just execution. Till he is master of those parts, and capable of instructing the men under his command, he is not to be permitted to take the command of a platoon in the battalion. Squads of officers must be formed, and exercised by a field officer. They must be marched in all directions; to the front, oblique, and to the flank. They must be marched in line, at platoon distance, and marched as in open column. They must change direction, as in file, and cover anew in column. In thefe, and other similar movements, the pace and the distances are the great objects to be maintained. From the number of files in division, they must learn accurately to judge the ground necessary for each, and to extend that knowledge to the front of greater bodies. They must acquire the habit of readily adapting, by the eye, perpendiculars of march, and the squarings of the wheel. An officer must not only know the post which he should occupy in all charges of situation, the commands which he should give, and the general intention of the required movement; but he must be master of the principles on which each is made, and of the faults which may be committed, in order to avoid them himself, and to instruct others.

These principles are in themselves so simple, that moderate reflection, habit, and attention, will soon move them to the eye, and fix them in the mind; and individuals, from time to time, when qualified, must be ordered to exercise the battalion, or its parts. The complete instruction of an officer enlarges with his situation, and at last takes in the whole circle of military science. From the variety of knowledge required of him, his exertion must be unceasing, every one driving to make himself master of his own part. Besides the instruction peculiar to the non-commissioned officers, they should be exercised in the same manner as the officers are, as they are frequently called on to replace them. The necessity also of order, readiness, silence, and of executing every thing deliberately, and without hurry, should be strongly inculcated on the infantry folder.

Formation of the Company.

The company is always to be fixed from flanks to centre. It is formed three deep. The files lightly touch, when firelocks are shouldered and carried, but without crowding, and each man will occupy a space of about twenty-two inches.

Close order is the chief and primary order, in which the battalion and its parts at all times assemble and form. Open order is only regarded as an exception from it, and occasionally used in situations of parade and fight. In close order, the officers are in the ranks, and the rear ranks are closed up within one pace. In open order, the officers are advanced three paces, and the ranks are two paces distant from each other. Each company is a platoon. Each company forms two sub-divisions, and also four sections. But as sections should never be left than five files, it will happen where
BATTALION.

where the companies are weak, that they can only, for the
purpose of marching, or three sections.

When the company is fully formed, the captain is on the
right, the ensign on the left, of the front rank, each covered by a
fifer, and a fifer is rear. The lieutenant is in the
rear, as also the drummer and pioneers in a fourth rank, at
two paces distance. The left of the front rank of each
subdivision is marked by a corporal. The right of the left
subdivision may be marked by another corporal. When neces-
sary, the places of absent officers may be supplied by fer-
jeants; those of fifers by corporals, and those of corporals
by intelligent men. When the company is to join others, and
the battalion, or part of it, to be formed, the ensign
and his covering fifer quitt the flank, and fall into the
fourth rank, until otherwise placed.

When the company is to take open order from close order,
on the command Rear Ranks—take open Order, the flank
men on the right and left of the rear ranks, step back to
the ground on which each rank respectively is to halt
and dref at open distance. They face to the right, and
stand covered. Every other individual remains ready to
move at the word of command March, the rear rank
drill front, and the rear ranks fall back one and two
paces; each drill by the right the infants it arrives on its
ground. The officers move out in front three paces, and
divide their ground. One fifer is on each flank of the
front rank. The pioneer remains behind the centre of
the rear rank. The drummer places himself on the right
of the right fifer.

When the company is to take close order from open
order, at the word of command Rear Ranks take close Order,
the officers, fifers, and drummer, face to the right. On
the word March, the ranks close within one pace, marching
one and two paces, and then halting. The officers move
round the flanks of the company to their respective posts:
The fifers and drummers fall back, and each individual
returns his place, as in the original close order. The above
regards the company when fingle; but when united in the
battalion, other posts are allotted to the drummer and
pioneer.

Formation and Order of the Battalion.

A perfect uniformity in the formation and arrangement of
all companies and battalions is indispensably for the execution
of just and combined movements. The strength of the
battalion is ten companies: one grenadier, eight battalion,
and one of light infantry, containing most commonly of
three officers, three fifers, three corporals, two drummers,
and fifty-seven privates. When these companies join, and the
battalion is formed, there is to be no interval between any
of them, grenadier, light company, or other; but every
part of the front of the battalion should be equally strong.
Each company which makes a part of the face line, and is
to act in it, must be formed and arranged in the same manner.
The companies will draw up as follows, from right to
left. Grenadiers, first and third captains; fifth and sixth
captains; eighth and fifth captains; second and fourth
captains, light infantry. The four eldest captains are on the
right of the grand divisions. Officers commanding com-
panies or platoons are all on the right of the front rank of
their respective companies. The eight battalion companies
will compose four grand divisions, eight companies or
platoons, six even subdivisions, and thirty-two sections, when
sufficiently strong to be divided, otherwise twenty-four,
for the purposes of march. The battalion is also divided
into right and left wings. When the battalion is on a war
establishment, each company is to be divided into two
platoons. When the ten companies are with the battalion,
they may then, for the purposes of firing or deploying, be
divided into five grand divisions, from right to left. The
battalion companies will be numbered from the right to the
left, 1, 2, 3, 4, 5, 6, 7, 8, the subdivisions will be numbered
1, 2, each; the sections will be numbered 1, 2, 3, 4, of
each. The files of companies will also be numbered 1, 2, 3,
4, &c. The grenadier and light companies will be numbered
separately in the same manner, and with the addition of
to those divisions. The several appellations will be preferred,
whether faced to front or rear.

The companies must be equalized in point of numbers, at
all times when the battalion is formed for field movements;
and could the battalions of a line also be equalized, the
greatest advantages would arise. But though from the
differing strengths of the battalions, this cannot take place,
yet the first requisite always must, and is indispensable.

Pil. III. fig. 2. When the battalion is formed in close
order, ranks are at the distance of one pace, except the
fourth or supernumerary rank, which has three paces. All
the field officers, and the adjutant, are mounted. The com-
manding officer is the only officer advanced in front, for the
general purpose of exercise, when the battalion is single; but
in the march in line, and in the firing, he is in the rear of
the colours. The lieutenant colonel is behind the colours,
and their advance guard. The major and adjutant are
in the rear of the third and fifth companies. The
chaplains are on the right of the front rank of each company
or platoon, and one on the left of the battalion. All these
are covered in the rear rank by their respective fifers, and
the remaining officers and fifers are in a fourth rank be-
hind their companies. It is to be observed, that there are no
covers in the centre rank to the officers or colours.

The colours, which in most regiments are carried by the
two youngest figers, are placed between the fourth and fifth
battalion companies both in the front rank, and each covered
by a non-commissioned officer or steady man in the rear rank.
One fifer is in the front rank, between the colours; he is
covered by a second fifer in the rear rank, and he is by a
third in the supernumerary rank. The fole function of the
third fifer is, when the battalion moves in line to ad-
vance and direct the march. The place of the fift of these
fifers, when they do move out, is preferred by a named
non-commissioned officer, who moves up from the super-
numerary rank for that purpose. Of the officers appointed
to carry the colours, the eldest carries the king's, the young-
est, the regimental colour. Whenever the right wing advances
or retires, the king's colour accompanies it on its flank,
and to it the men's eyes are directed as their point of de-
velop. In the same manner, the regimental colour accom-
plices the left wing.

The fourth rank is at three paces distance when halted,
or marching in line. When marching in column, it must close
up to the distance of the other ranks. The essential use of
the fourth rank is to keep the others closed up to the front
during the attack, and to prevent any break beginning in the
rear. On this important service too many officers and
non-commissioned officers cannot be employed. The pioneers
are assembled behind the centre, formed two deep, and nine
paces from the third rank. The drummers of the eight
battalion companies are assembled in two divisions, six paces
behind the third rank of their second and seventh companies.
The grenadier and light infantry drummers and fifers are
six paces behind their respective companies. The
musicians are at three paces behind the pioneers in a single
rank, and at all

The half of chaplain, furgeon, quarter-master, and furgeon's
aid,
affendant, are three paces behind the music. Officers in general remain posted with their proper companies; but commanding officers will occasionally make such changes as they may find necessary. Whenever the officers move out of the front rank, in parade, marching in column, wheeling into line, or otherwise, their places are taken by their lieu-tenant coverers, and preferred until the officers again resume them. When the line is halted, and especially during the firing when engaged, the freijant coverers fall back into the fourth rank, and observe their platoons.

Pl. III. Fig. 4. When the battalion is to take open order, at the word of command Rear Ranks take open Order, the flank men on the right of the rear ranks of each company step briskly back to mark the ground on which each rank respectively is to halt. They face to the right, and cover as pivots, being regulated and dressed by the Adjutant or freijant major on the right. Every other individual remains ready to move. At the word March, the flank dress face to the front, and the whole move as follows:—The rear ranks fall back two and two spaces, each dressing by the right the instant it arrives on the ground. The officers in the front rank, as also the colours, move out three paces. Those in the rear, together with the music, move through the intervals left open by the front rank officers, and divide themselves, viz. the captains covering the second file from the right; the lieutenants the second file from the left; and the ensigns opposite the centre of their respective companies. The music form between the colours and the front rank. The freijant coverers move up to the front rank, to preserve the intervals left by the officers. The pioneers fall back to six paces distance behind the centre of the rear rank. The drummers take the same distance behind their divisions. The major moves to the right of the line of officers. The adjutant to the left of the front rank. The staff place themselves on the right of the front rank of the grenadiers. The lieutenant colonel and the colonel (dismounted) advance before the colours, two and four paces. The whole being arrived at their several posts, the words Halt—Dress are given to the respective companies, and the battalion remains formed for parade in the order in which it should receive a superior officer. When the battalion is reviewed singly, then in order to make more room, the division of drummers may be moved up, and form the two deep on each flank of the line. The pioneers may form two deep, on the right of the drummers of the right; and the half may draw up on the right of the whole.

When the battalion is to resume close order, the words Rear Ranks take close Order is given. The lieutenant-colonel, officers, colours, flag, and music face to the right. The drummers and pioneers, if on the flanks, face to the centre. The freijants, it in the front rank, face to the right. At the word March, the rear ranks close within one pace, moving one up and two spaces, and then halting. The music marches through the centre interval. The freijants, drummers, pioneers, &c. resume their places, each as in the original formation of the battalion in close order. The officers move through and into their respective intervals, and each individual arrives, and places himself properly at his post, in close order.

On particular occasions, and when necessary, officers commanding platoons, who in line are on the right of their platoons, shift to the left to conduct the heads of files, or the pivot flanks of their divisions, in echeelon, or in column. When the battalion wheels by companies, or sub-divisions, to either flank into column, both colours, and the file of directing freijants always wheel to the proper front, and place themselves behind the third file of the new pivot.

There is no separate colour referee, the pioneers, music, &c. sufficiently strengthen the centre; but in the flanks, the two files on each side of the colours may be ordered to receive their fire.

The constant order of the light company, when formed in line, and united with the battalion, is at the same close file as the battalion. Their extended order is an occasional exception. When the light company is detached, and the grenadier company remains, it will be undivided on one flank of its battalion, whenever there are several battalions in line; when the battalion is single, it is permitted to be occasionally divided on each flank. When the grenadier or light companies are detached, and make no part of the line, they may be formed two deep, if it is found proper.

With a very few obvious alterations, these general rules take place when a company or battalion is permitted or ordered to form in two ranks only; and which, on the low establishment of our battalions, may often be done for the purposes of exercise or movement on a more considerable front. It is also evident that they generally apply, whether the companies are strong or weak, and whether a greater or lesser number of them compose the battalion.

We shall now proceed to give an abstract of the most essential general attentions required in the movements of the battalion, and which may be found more fully detailed in the rules and regulations for the battalion and the line, as published by his majesty's command.

I. Attentions of the Soldier.

Quick time is in general confined to wheelings and filings. The other movements of the platoon or battalion are made in ordinary time. It is seldom that they will, or ought to be, required at quick time. All wheelings, forward or backward, are made quick. Eyes are turned to the wheeling flank, at the word March, and not before. The wheeling flank man steps out firm at a pace of thirty-three inches, till he receives the word Halt. It is the business of the rest of the rank to keep up to him. Eyes remain in all cafes to the wheeling hand, till a new order is given by the commanding officer. All filings are made quick, close, and at the lock step. Files are at no time to open out, on occasions of exercise, parade, or manœuvre; but they will often be permitted and ordered, when marching in the streets; or in common route marching, when the march by divisions cannot be conveniently take place. All filings must be accurately made on the left heel. Pivot men must cover carefully and exactly. In wheeling backward, the flanking man faces the opposite way to that he does in wheeling forward. Pivots, whether in wheeling into column, or in wheeling into battalion, when once filled are to remain immovable and do not alter their position in consequence of platoon dressing, nor on any account, but by order of the commanding officer of the battalion, when he finds it necessary to require a more correct dressing from the whole.

The great observance of the soldier in the ranks, and under arms, is the squareness of the shoulders and body, the head to the front, and eyes only glanced to the point of dressing. When the battalion is halted, and a more accurate dressing is ordered, the head may be a little turned during that operation only, and each man should just dilate towards the lower part of the face of the second man from him. Whether in movement, or halted, each man is just to touch, without crowding, his neighbour's arm, towards which he drefles, to depend on that chiefly for his line, and at no time to separate from him. At the word March, the flamp of the foot is not to be made, but the thill flaps is to be taken as firm and long as any other, and the body of each man, if in his true position under arms, is prepared for it by an inclination forward.
forward. On the perfect execution of this depends much of the accuracy of march. On the word March, the first step in all situations is taken with the left foot. When the command- ing officer of the battalion gives the word, the whole file off, whether in line or in column. When he gives the word Halts, the whole halts. The right word March are directed to the pivot flank, if in column; or to the head of the file, if filing; to the colours, if marching in column; and in general to that point by which they are conducted. At the word Halts, the foot in the air finishes its step, and the other is brought up to it.

Eyes remain directed to the pivot flank if marching in column; to the colours, in line; or to the wheeling flank, if wheeling; and in general to the point to which they were turned when in movement, until a new order commands a new drilling. Whenever the word Draw is given by platoon officers to their platoons, eyes are turned to the pivot where the officer is, and from whence he corrects them upon a distant object. In marching in line, each man must preserve his body perfectly square, and just feel the touch of his neighbour, March's nearer than himself to the directing point. The rear ranks are to be well locked up, particularly when firing. In marching in battalion, or when halted, rear ranks will be locked up; but in marching in column, they may in general be at one pace distance. The files are to be taken firm, and marked.

All alterations in carrying, supporting arms, &c. are done by the whole battalion at once, whether in line or column, and not by the divisions of it separately. The commanding officer gives the word, and not the platoon officers; and no such change is at any time made, but in consequence of his command. The men therefore, in all cases, wheel halt, march, draw, &c., with their arms carried, supported, trailed, or flapped, according as the last given command directed them. The same is to be observed whenever the battalion, moving in line or in column, changes its time of march.

In column, when the right of the battalion is in front, the left is the pivot flank; and when the left is in front, the right is the pivot. In marching in column, the pivot files of men next to the officers must have great attention in covering, when the movement is made in a straight line, as they are points on which the formation is made; and therefore for that purpose, they must remain close to their pivot officers, who in that situation cover and give distance.

Supported arms should only be allowed when halted in line, or when moving in column. But the march in line, and in general all wheelings up in line, and all formations of the line or drilling it, should be made with carried arms, as the only situation which preserves the true distance of files, or can give an accurate line.

II. Covering Platoon Sergeants.

The covering sergeant accompanies and assists the platoon officer in all his movements, and prefers his place in line, or on the pivot flank in column, whenever the officer's duty requires him occasionally to quit it. In battalion, he covers in the rear rank. At open order he moves into the officer's place in the front rank. At close order, he leaves it for the officer to take it. In the march in echelon, lie is on the outward flank of the front rank. When the battalion breaks into column to the right or left, the sergeant falls back two paces; and when the wheel is finished, he covers his officer on the pivot flank. When the column marches, if the officer is in front of the platoon, the sergeant is on the pivot of the front rank, and is answerable for the platoon distance; if the officer remains on the pivot flank, the sergeant then falls behind the rear rank, and covers the second file from the pivot. When from column the right in front platoons wheel up to the left into line, the sergeant at the word Wheel, goes to the right of the front rank of the platoon, and wheels up with it, thereby preferring the officer's place. If the wheel is to the right, the sergeant is behind the right file, ready to move up to the officer's place at the conclusion of the wheeling. On all occasions, when any particular order is given to the sergeant on the right, to prefer the place of his officer, who may be employed in dressing his platoon.

When the platoons wheel either into line or into column, the sergeant of the leading platoon runs out, and marks the point in the line of the pivot where its flank is to halt. When platoons countermarch in column, the sergeant moves into the officer's place on his quitting it to lead in line, faces to the right about, stands fast, and becomes the pivot point for the front rank leader to close to after the countermarch is finished, and its place is occupied by the officer after dressing his division. When the platoons from column files, in order to take a new line either to the front or rear; the sergeant of each successively, as it arrives within thirty yards of that line, and no longer, runs out, takes distance, places himself upon it, and remains as a point to which his officer is to bring and clothe in the pivot flank man of his platoon, and as a point which the officer himself is afterwards to occupy. Whenever the battalion halts to fire, the sergeants fall back, and in concert with the supernumerary rank, keep the rear ranks well locked up and attentive to their duty. When the battalion again moves, sergeants resume their places. When the battalion is in column of subdivisions, if the officer is ordered to march in front of his platoon, the sergeant is on the pivot of the leading subdivision. If the officer is on the flank of his leading subdivision, the sergeant takes the flank of the second. In column of sections, the sergeant also takes the flank of the second section. In close column, the sergeant is on the flank of the rear rank, behind the officer; and in forming line after the Halt, Front, of the platoon, he remains on its outward flank, and marches up with it.

The pioneers, in column of march, are in front; in line, they are formed two deep behind the centre, and nine paces from the rear rank. Drummers, in column of march or close column, are with their companies, and on the flank not the pivot one. In line, the grenadier and light drummers are fix paces behind the rear rank of their companies. The battalion drummers are in two divisions, and formed fix paces behind the third and seventh companies. In parade, at open order, the drummers preserve their fix paces from the rear rank. Whenever the platoon is cautioned to wheel forward or backward any named number of paces, the sergeant immediately posts himself before or behind the eighth file from the flank, and takes the ordered number of paces; when his platoon has conformed, he places himself on its outward flank. The mute, in open or close column, are on the flank which is not the pivot one; in line, they are in single line behind the centre, twelve paces from the rear rank. On parade, at open order, they are between the colours and the front rank. Drummers, mutes, pioneers, &c. will take care not to impede the flank movements of the close column, nor its formation into line, but will get into the rear of their respective battalions, as soon as they are detached from each other.

III. Attentions in Platoon Officers.

When the battalion is formed in line, company or platoon officers are all on the right of their platoons. In column, they are on the pivot flank, unless particularly ordered into the front of each platoon, if a march for any considerable distance is to be made. When on the pivot flanks, they are
are answerable in their own persons for distances and covering. When in front, their sergeants, under their direction, preserve the ordered distance.

In wheeling from line to column, each moves out, and places himself one pace before the centre of his platoon. Each turns towards his men during the wheel, and inclines to his pivot flank. Each gives his word, 

**Hal—Draf**, when his wheeling man has just completed his degree of wheel. Each squires his platoon, but without moving what was the flanking flank. Each then places himself on the proper pivot flank. After the wheel into column is completed, no one is to cause his platoon to shift, by way of covering on the pivot flank, unless so ordered by the commanding officer, or that in the course of marching a straight line is gradually taken up. In wheeling from column into line, the officer places himself one pace before the centre of his platoon, turns towards his men during the wheel (inclining towards the pivot of his preceding platoon), and gives the word 

**Hal—Draf**, when his wheeling man, on whom his eye is fixed, is just arrived at the next flanking pivot man. He then, from that pivot man correcting the interior of his platoon upon his own pivot man, takes his place, and remains steady on the right of his platoon.

If the column is in movement, and platoons are successively to wheel into a new direction, each officer, to whatever hand he is to wheel, gives the word from the point he is then placed at, whether in front or on the flank. If on the wheeling flank, he conducts it; if on the flanking flank, he steps out two or three paces, the better to see that his platoon wheels quick, with a proper step, and that he may time his word 

**Hal**. This done he is to fall back to his place on the pivot flank, no longer to look to his platoon, but having his eye fixed on the officer of the preceding platoon, he is to give his word 

**March** to the infant officer that officer is then taking the last step which establishes the proper distance between the platoons. When an officer is marching on the pivot flank, he is to be answerable for distance and covering. These circumstances alone must solely engage his attention: he can only occasionally give a glance of his eye towards his platoon, which must drest to him of course, and without any particular direction.

When platoons in column are each to countermarch on its own ground, the officer, when his platoon faces, goes to that flank which is to become the pivot flank, conducts his platoon in file, and closes his leader to the serjeant, who has remained to mark the pivot, 

**Halts, Fronts, and Drests it square.** He then places himself where the serjeant stands.

When the battalion marches in line, officers then become individuals, equally attentive as the soldier; nor can officers then be attentive to any thing but to the correctness of their own personal march. Every operation then depends on the word from the commanding officer, who moves, halts, and drests the battalions. Whenever the battalion is in line, officers give no commands except in fringes.

When the platoons of a column file separately to a flank, the officer conducts the head; and when he arrives within thirty paces of the new position in which he is to form, he detaches his serjeant to mark the point at which he is to place his pivot front rank man, either in filing to front or rear. The officer files at that serjeant, and halts, fronts, and drests his platoon close to the serjeant. He then himself, after correcting his platoon, replaces the serjeant, who falls back to the rear rank. In filing, distances and dresting are taken from that hand to which, by a face of the platoons, the whole will stand fronted in column, and the line breaks into column towards the dresting point. The leaders of the third, fourth, &c. platoons from the directing flank are never to overpass the straight line which joins the heads of the first and second, but are, if any thing, to be behind it, till they arrive and halt exactly in the new line. In movements to the rear, distances and dresting are always taken from the same point to which they would be made, if the movement was to the front; that is, from the left in going to the rear, if it should be from the right in going to the front.

On the leading platoon officer of the column much of the precision of march depends. He must lead at an equal, steady pace, and on two objects either given to him, or which he himself takes up on every alteration of position. This demands his utmost attention; nor must he allow it to be diverted by looking at his platoon, the care of whose regularity depends on the other officers and non-commissioned officers belonging to it. The second platoon officer must also be shown, and known, the points on which the first leads. He is always to keep that first officer and those points in a line; and those two officers, together with the placed mounted officers, thus become a direction for the other pivot officers to cover. In marching in open column, the covering serjeants are placed behind the second file from the pivot officers, that the officers may the more correctly see and cover each other in column. In the column of march, after the word **Halts** is given, no one is to move, and pivots particularly must remain where they are then placed. In this situation, when ordered to form, each platoon wheels up to its adjoining pivot; the whole then perhaps, as in the case of marching upon a road, along the different turnings of a height, &c. &c. be on a winding line, and must not attempt to get into a straight line, unless so ordered by the commanding officer to answer some particular object. When the platoon wheels **backwards** from line into column, the situation and business of the officer are the same as when wheeling forwards; and he halts and drests from his pivot flank, which he gains during the wheel.

In close column, division officers are on the pivot flanks. In forming line, before the divisions face, they are shifted to the leading flank, if necessary. The officer of each file in his own person, when the division nearer to the forming point than himself, receives the word 

**Halts, Fronts**, allows his serjeant to proceed with the division; at the due instant gives his word 

**Halts, Fronts—Drests**, and as soon as the front of his division is clear, the word 

**March**, conducting it into line. Before the division arrives within three or four paces of its ground, the officer will have stepped out nimbly to the flank of the preceding division, and will be thus ready to give the word 

**Halts—Drests** at the instant his inward flank man joins the preceding division. The men drest from the formed part of the line, and the officer corrects them on the known distance point. He then resumes his platoon place, which has been preserved by a serjeant. When the close column, or part of it, forms line on a rear division, the officer of each, when the one behind him halts, fronts, will step nimbly round the rear, and without impeding his division, allow his serjeant to proceed. From hence he can better judge the proper moment of giving his words 

**Halts, Fronts, to his division.** He then places himself on his inward flank, and marches up when his front is clear. The officer of one of the centre platoons is always in open column, to preserve distance for the colour files. The colours wheel up into column, with the leading centre platoon, and place themselves behind the third file of men from its pivot flank. When the line forms, they close in to that flank.

When officers march in front of their divisions, they must in their own persons keep close to the preceding ones, as not to hinder the flank of their own division from preserving
ing its proper distance. When the head of a column of march changes its direction, and that marching in an alignment is not in question, instead of making regular wheels on fixed points, the officer who conducts the leading division will often be directed to bring it gradually round into the new direction, by the turn of the outward shoulder, making both its flanks continue movable; but each succeeding division, without the formality of command or hint, does the same thing, the whole attention retiring on each pivot flanks, which at no rate must inhere its distance, but during this operation preserves the same equality of time and length of Rep at which it was before moving. On all occasions of forming in line, either by wheeling up from open column, or in moving up from close column, or in marching up from echelon, &c. the conducting officer moves nimbly to his point of appui, some paces before the arrival of his division in the line, and from thence gives his word to Halt, and instantly dreses it.

Officers and SERjeants of the supernumerary rank are in the rear of their respective companies. When the battalion is halted, or marching in line, they are three paces from the rear rank. In open column, they are within one pace of the rear rank. In close column, they go on the flank of their division which is not the pivot. Their great attention during movements is, that files are correct, ranks kept up, and that perfect order is preserved among the soldiers; circumstices in which they greatly affix the platoon officer, who has the more important objects of distance and the covering of pivots to observe, cannot in such situation he giving minute directions to his platoon, without loosens his more material duties. During the frigings, the supernumerary rank, affixed by the platoon SERjeants, are to keep the rear ranks well closed up to the front, and to prevent any break beginning in the rear.

The staff (adjutant excepted), in line, are three paces behind the music; in parade, at open ranks, they are on the right of the grenadier front rank. It is the particular busines of the adjutant at all times to ascertain the direction on which the column is to move, or on which the formation of the line is to be made. For this purpose he is mounted; otherwise he could not properly discharge this important duty; and he can be much affixed in doing it, by having two or three camp colour men, or non commissioned officers, properly trained to line themselves quickly with any two given points. He is to take care that the point where the battalion in column enters an alignment is ascertained to it; when it is moving in that alignment, that two points ahead of the column are always prepared; when it wheels up into line, that a point beyond each flank of that line is ascertained; when the line is to be prolonged, and has wheeled backward by divisions, that two points in the exit line of the pivots are ready for its march; when the close column is to form in line, that a point to each flank is given; when the battalion changes position, either by files, or by the diagonal march of divisions, that there are points given on which the pivots of files will cover, and can dres their divisions upon from their several points of appui; short, that upon all occasions, fixed points of forming, drafting, and march, are given, except in advancing in line, where the ascertaining such points does not depend on the adjutant.

When the battalion changes position, by the echelon march, the named division wheals its eighth file into the new direction. The other divisions wheel their eighth file half the number of paces as the named one. The SERjeant is on the outward flank, the officer on the inward flank of each division. At the word March, they move on, preferring their relative distance, and covering of pivots from before them, and just before the inward flank of each division arrives at the outward flank of its preceding one, which is already halted in line, its officer places himself before that flank; and when his inward man touches it, he gives his word Halt,—Dress up, if the movement is to the front, and dreses his division on the distant prepared flank point, to that his division is steadied before the arrival of the next one. When the change is made to the rear, the retiring part faces about before the division wheels are made, proceeds as above, and each officer gives the word Halt, FRONT, Dress—

BACK, to his division when its inward man touches the preceding formed one.

IV. Attention of Commanding Officers of Battalions.

The battalion may be considered with respect to the line, what the platoon is to the battalion.

Commanding and field-officers are always to be mounted, and unless they are active on horseback, it is impossible for them to see, to correct, to prevent mistakes, or to move with that dispatch which is necessary from one point to another. Whatever operation is to be performed by the whole of the battalion at once, is done upon the word from the commanding officer, without any repetition being made by platoon officers. He puts it in motion, and halts it, whether in line or in column. He wheels it from line into column, and from column into line. He orders arms to be carried, supported, &c. He dreses it from the centre, when it has marched in line, and halts; and from what was the leading flank when it has wheeled up from column into line.

Before the column marches, the commanding officer ascertains points to the leading officer; and when he intends to change the direction of the march, he gives new points, and he watches over the just leading of the column. He takes care that all wheels of platoons are made at the identical point where the leading platoon wheeled; that all doublings of subdivisions are made successively in the same manner and at the same point; and that forming up to platoons is made at the spot where the first forming up is made; that in all diminutions of the front, the natural order of the column is preferred, whether the right or left of the battalion leads; that a column of half platoons occupies no more space than a column of whole platoons, viz. just enough to wheel up into battalion.

When the open column marching in an alignment is to form in a straight line, and for that purpose halts; the instant that it does halt, the commanding officer from the head of the battalion corrects the pivot files of men (which ought not to be necessary) in the true line, and upon a rear point. But if the march is making in a winding direction, and that the intention is not to form, or not to take up a straight line, the platoons remain on the ground on which they halt, and do not move in any shape, until they receive a further order, either to form in line, or first to cover, and then to form or continue the march. The commanding officer always conducts the head of his battalion column to the point at which it is to enter a new line, and he takes care in time to dispatch a mounted officer to ascertain that point. When the platoons wheeled up into line, he immediately, if necessary, corrects the Dressing of the battalion from the flank which led when in column, and that generally upon a point by yond the other flank.

When acting in line with others, the commanding officer of each battalion conforms to the movements of the regulating one, and he repeats, and rapidly repeats, his words of Halt, Wheel, March, &c.; and the least delay in repeating any of these words must undoubtedly disordered the line in proportion to that delay, for the whole of a line should march or halt at the same instant. In line, the commanding officer
BATTALION.

The officer is in the rear of the colours. From thence, by marked
cautions, he makes his battalion step out, or step short, or
march, as is necessary to preserve its place in the general line.
His great care is to see and prevent the beginning of faults,
and not wait till they have had effect. By watching and regu-
lating his advanced serjeants, he keeps regulates his battalion. The
regularities of the march, the compacts of the files, and the equality of
step, are the great objects he is to have in view. The other mounted
officers are behind the wings, and can assist much in preventing faults,
and in correcting them.

All the battalions of a line must halt at the same instant
in conformance of that word, repeated by commanding
officers, whether they are then correct, or not in line. Each
battalion from its own colour, and the men looking to
it, will be immediately dreeled on the colours of the next
adjacent battalion. By this means a general continued line
will be obtained, or, at any rate, a straight line between each
two colours; and if all the colours halt truly halted
in one line, the whole corps will be completely formed in a
straight line. But if the halt is not justly made, and that
a better line must be obtained, the colours of the defective
battalions will be brought into the general line; the platoon
officers will quickly arrange themselves, eyes will be or-
tered to the right, and the men will in an instant move
up. Too much celerity cannot be used in completing this
operation.

A single battalion, when it halts, is dreeled on its right or
left centre company, and is therefore in a straight line.
Two battalions dree each from its centre on each other's
colours, their outward wings conforming, and are therefore
in a straight line. Three or more battalions dree from the
centre of each, on their next colour; and therefore if all the
colours halt in a line, the line of the whole will be straight;
if they are not so halted, the general line will not be dreeled,
till a special correction is made, but no flank will be thrown
out of the general direction. When a battalion retires and
halts, it ought never to remain in that situation, but be im-
mEDIATELY about, and dreeled to the proper front. The
first fault that a battalion in line can make, is increasing its
interval. But dreeing may be remedied without danger,
but a false distance presents a weak part to the enemy, and
is not to be closed without a hazardous movement, and great
operation of the line. Commanding officers cannot take
too much precaution to ascertain true points in the line in
whem they are to form, before the arrival of their battalions
in it. When a battalion is exerting fittingly, a commanding
officer may have two camp colour bellers behind each flank,
properly trained, and ready to run out to that flank, to give
points of marching, forming, or dreeing upon the true line;
in doing which, one flank of the battalion is generally con-
sidered as in that line, and often both.

Words of command cannot be specified for all the variety
of circumstances and situations that occur, but commanding
officers, being themselves clear in what is to be done, should
by distinct and explicit orders, which they divide and adapt
for the occasion, lead their battalions through all the points
of execution with precision. This will always be found
the shortest path, nor on any account should any operation,
more especially the correction of an error or mistake, when
once a battalion is assembled under arms, be performed in a
careless or flabby manner, which will always be the case if
the commander's orders be not pointed, loud, and sufficiently
explanatory.

A battalion close column forms in line on its front division,
on a rear division, or on a central one, according as circum-
stances require; and in all cases the line formed upon is that
on which the head of the column or columns is halted before
the formation begins. Therefore the division on which each
battalion halts may at any time form, move up at their own
halt, and halts on that line. When several close battalion's stand-
ning on the line, are to extend and form, the regulating and
named battalion only can be obliged to form on a central
division. Each of the others will form on its front or rear
division, viz. on that which first arrives at its ground where
it halts, fronts, and occupies its proper place, while the others
move on, and successively come up to it. In forming
line from close column, points must be given beyond both
fronts in the direction of the line, and a mounted officer
halts, and fronts each division, which is especially necessary
for those that form upon a rear one, although left fo for
those that form upon a front one. The dreeing and cor-
rection of the line is from the first formed division towards
the other flank, and all the eyes of the battalion are of course
turned to that first formed division.

The same number of points are required for the march
into an alignment, and wheeling up into line of an open col-
umn of one battalion, as for that of several battalions; viz:
one where the line is entered, and always two beyond the
head of the column. Therefore, although these precautions
may appear formal for the movements of the battalion when
single, yet they are necessary in all its exercises, when it is
recollected, that such battalion is in the place of, and must
consider itself as the leading one of the column, on whose
correct position that of every following one depends. The
same exactness is required in every extension from close
column into line, and in every forming and change of posi-
tion that the battalion makes. In line, in order to qualify
the battalion for acting in the general line, it must at its
single exercises work on points fixed and relative, and make
no chance and accidental movements or formations. Al-
though on most occasions of movement and formation, and
at all times in instruction, determined points marked by de-
tached and mounted officers are given; yet such helps can-
not be expended or depended upon, when the line is ad-
vancing on an enemy, when a corps is harassed in its retreat,
and when it is unsafe to send out officers, &c. In such situ-
ations every thing will depend on the eye and judgment of
conducting officers, who must preserve their direction of
movement, and seize such accidental points as present them-
seives, and lead to the object which is to be accomplished.

In whatever phase a battalion is moving, the commanding
officer is never to lose sight of this great principle, that the
battalion should at no time cover more ground than its proper
extent when formed in line. Therefore if he is marching in
line, he must take care that his files do not open; if in co-

dumn, his great attention should be, that his divisions do not
open. For this purpose his march must be just and compa-

tic, his wheels quick, and all doublings up, or back, which
alter the extent of front, must be made so as not to impede
the general movements of the column, or to change its
distances. When the front is to be diminished, he must see
that the doubling division slackens its pace, and when dis-
genengaged from the other division, that it inclines well up,
quick, and covers, so as not to impede the division in its rear.
When the front is to be increased, the moving up division
does it quick, and by a bilque marching.

The commanding officer must recollect, in the winding
motions of the open column of march, that the wheeling
distances must be just; that the pivots are to follow on
the exact track which the leading one has traced out; that the
whole, when ordered, halt on the precise ground they then
occupy; and that when they wheel up, in form, the line
will not then be a continued, but probably an irregular curved
one.
Battalion.

Regiments should have an attention to give their commands in such manner as not to produce an alteration in those points that are not meant to be influenced by them at that instant.

Where a large body is marching in column or columns, through a narrow ground, and when its parts are to be assembled beyond the defile in several lines, in a compact manner behind each other, such parts are not to begin to advance when the leading one does, but the head of each line is successively first to come up to the ground on which it is to stand, and when it there stands, its proper followers, and not before, move into line with it; thus not impeding the divisions that are behind them in the defile, and are to perform the same operation.

Precision of movement depends altogether on the instant circulation of commands of execution and on the attention of officers to the point they may be expected to come from. Unless the whole of a body, however large, is put in motion at the same instant, a column will be extended badly, and a line will be ill drested, and with false intervals.

Officers must particularly attend to the difference between changes of direction made by wheel, and by shoulders forward.

In the first case, one flank remains fixed, while the other is on the wheel; in the second, both flanks are in motion. Shoulders forward applies to a small front, and to a column of march, where the change of direction is to be made gradually without an alteration of the pace. In proportion to the front of the body to changing, must be the degree of sweep made by both flanks; and in all cases, the reverse flank conforms to the pace of the pivot flank. In no case can it be made short and quick, otherwise it becomes a wheel.

Regulations in Firing.

1. The advance of the battalion should instantly succeed the forming of the line, and when it arrives and halts at the point where it is to fire, the firing ought instantaneously to commence at the word Halé, for the battalion having been aprized, during the march, of the nature of the required firing, no improper delay need therefore be made. The greatest care should be taken by the officers and non-commissioned officers in the rear (whole principal attention this is) that the rear ranks are well locked up in the firings, and that in loading they do not fall back.

2. The pause between each of the firing words Make ready—Present—Fire, is the same as the ordinary time, viz. the 7th part of a minute, and no other pause is to be made between the words.

3. In firing wings by companies, each wing carries on its fire independent, and without regard to the other wing, whether it fires from the centre to the flanks, or from the flanks to the centre. If there are five companies in the wing, two pauses will be made between the fire of each and the make ready of the succeeding one. If there are four companies in the wing, three pauses will be made in the same interval. This will allow sufficient time for the first company to have again loaded, and shouldered at the time the last company fires, and will establish proper intervals between each. In firing by wings, one wing will make ready the instant the other is shouldering. The commanding officer of the battalion fires the wings.

4. In firing by grand divisions, three pauses will be made between the fire of each division and the make ready of the succeeding one. In platoon firing, two pauses will be made. In firing by subdivisions, when once fires, the next presents; when one presents, the next is ready; thus keeping up an incessant fire.

5. In firing companies by files, each company fires inde-
pendently; when the right files present, the left make ready, and so on. After the first fire, each man as he loads comes to a recover, and the file again fires without waiting for any other. The rear rank men are to have their eyes on their front rank man, and be guided by, and present with them.

5. In general, after the march in front, and halt of the battalion company, or platoon firing, should begin from the centre, and not from the flanks. In other cases, and in successive formations, it may begin from whatever division first arrives, and halts on the ground.

6. The line, if retreating, Halt, fronts, at one command, and infantry begins firing, from the centre and not from the flanks.

Observe of Fire.

I. Against Cavalry. The chief object of the fire against cavalry is to keep them at a distance, and to deter them from the attack. As their movements are rapid, a reserve is always kept up. But when the fire commences against infantry, it cannot, consistent with order, and other circumstances, be too heavy or too quick, while it lasts, which should be till the enemy is beaten or routed, or till the contest becomes too unequal. The fire of three ranks standing, is barely, with our present arms, to be required, especially if the front should be broken, and the flanks loaded with their knapsacks. The fire of the rear rank, therefore, is generally reserved.

II. Defensive Fire. Where infantry are posted upon heights that are to be defended by the fire of musquetry, the front rank will kneel, that one third of the fire that may be given should not be lost; otherwise the rear rank in such a situation could not sufficiently incine their pieces to raise the slope. As soldiers generally present too high, and as fire is of the greatest consequence to troops that are on the defensive, and who are posted in such positions; the habitual mode of firing should therefore be rather at a low level than a high one; and the fire of the front rank kneeling being the most efficacious, as being the most rapid, should not be despised with when it can be safely and usefully employed.

III. In Line advancing. When infantry marches in line to attack an enemy, and in advancing makes use of its fire, it is preferable to fire the two first ranks only standing, than to oblige the front rank to kneel, thus firing the whole. But volleys, fired at a considerable distance, or on a retreating enemy, may be given by the three ranks, the front one kneeling.

IV. Platoon Firing. A line posted, or arriving at a fixed situation, will fire by platoons, each battalion independent, and such firing generally commencing from the centre of each. The first fire of each battalion will be regular, and establish intervals. After the first, each platoon shall continue to fire as soon as it is loaded, independent of any other, and as quick as it can, till the battalion or line is ordered to cease.

V. Independent, or File Firing. If behind a parapet, hedge, or abattis, the two first ranks only can fire, and such firing may be file firing, and may be made deliberate and cool, the two men of the file, always firing together. It may begin from the right or left of platoons, and should be taught in situations adapted to it, not in open ground. Should the parapet, hedge, or abattis be but little raised, platoon firing may be used.

VI. Running Fire. Troops should be often practised in executing the billebands, or running fire. This should begin on the flank files, and when once commenced, continued without the soldier being subject to any other rules than keeping silence. This sort of firing is the only one which infantry should make use of in engagements. It is the most lively, and more dangering than any. It enflames and warms the soldier, and renders him incendiary to danger. The grand point is to accustom troops to leave it off when a signal is given, and afterwards remain silent.

VII. Oblique Firing. Oblique firing by battalions is advantageous in many occasions. As when attacked in an oblique direction; when time does not allow to give an obliquity to a greater part of the line; and when their fire can in this manner be thrown again the opening of a defile, the flanks of a column, or against cavalry or infantry that direct their attack on some particular battalion or portion of the line.

VIII. Regularity of Firing. As long as the fire by battalions is oblique, wings, or by platoons, can be kept up regular, it is highly advantageous, and can at any time be stopped; but should filing be allowed, and one begun, unless troops are exceeding cool and well disciplined, it will be difficult to make it listen, and to make them advance and charge in order. When a line halts at its point of firing, no time is to be lost in keeping division, and the fire is to be commenced, but a line is kept back, and is not to fire, or when its firing ceases after the halt, it may immediately be ordered to descend from colour to colours.

IX. Street Firing. It is so called from being obliged to engage in a street, highway, lane, or narrow passageway, where no more than 10, 12, 16, or 20 files can march abreast; so that, according to the breadth of the place, the platoons must be stronger or weaker. When the column is in motion, and arrived where the firing is to begin, the commanding officer from the rear, gives the word Halt. The officer commanding the platoon instantly gives the words ready, present, fire; recover arms, outwards, quick march. At the word recover arms, the platoon immediately in the rear of the one that has fired, recover their arms also, and march, and when their front is open by the march of the others down their flanks, they march on with recovered arms, until they receive from their officer the words halt, present, fire, &c. As soon as the platoon has got down the flanks, it must form instantly in the rear, and immediately prime and load again without halting, keeping always their exact distance from the division before them, which would not be the case if they halted to load and shoulder.

When this is to be put in practice on real service, the front of the platoons must not be equal to the breadth of the place they are to engage in; but there must be a small space of ground, or interval, left on the flanks, for those who have fired to have room to march back, and form in the rear. It is in this manner, when there is not time to raise a breast-work, that a paf, bridge, road, or street to be maintained against the enemy, by the platoons advancing one another, and firing in their turn, which may be continued as long as there is occasion, almost without interruption, by one battalion only. In firing as above described, the colours, &c. must at the first be placed in the rear, and kept thereby the subdivisions, as they come down the flanks after firing, forming confiderably in their front, till the whole business is over.

There are, however, different methods, of retiring the platoons from the front to the rear. Some are instructed, after the word fire, to recover their arms, and wheel out the platoon by subdivisions from right to left, load, and remain in that position till the last platoon paffes them, when they wheel back, and form. Another method is, supposing the street to be filled by the platoon, and no room left on the flanks, then by throwing back or retiring a centre section of
of each platoon, the retiring division may pass through the centre of the column to the rear. It looks well, and has a good effect on a day of parade; but it is too complicated to be attempted with Lifity in the presence of an enemy.

**General Directions.**

There is no doubt but that the fire of the musketry may be reduced to a theory; but far from that being the case, the soldier has no principle given him, for at the distance or situation of the objects, be they what they may, he fires at random. It is principally owing to the exercise of the target being so little practised, that this ignorance and deficiency of principle are so frequently felt.

In our firings, the soldier is instructed always to fire low, yet no reason is given him why it should be so, but that the ball rises. To consider this a moment; the line of level [The line of level is the straight line by which is seen the object on which the ball should be carried to.] and the line of fire [The line of the fire is a straight line which represents the axis of the musquet.] are by no means parallel; for according to the different weights of metal which the barrel has at its breeching, and at its aperture, so do they describe an angle more or less acute beyond the tube. As the eye seeks its aim from the length of the line of level, it is therefore fixed at the exterior of the barrel. But entirely different to this principle, the motional body, the bullet, is impelled from the interior part of the instrument, and the length of the line of fire; therefore the line of fire and the line of level cut each other. From the law of attraction imparted on all bodies obliquely thrown, at its delivery from the mouth of the cylinder, the bullet or ball describes a curve, which rising from the muzzle, cuts the line of level at a small distance from the mouth of the barrel. It will, at about the distance of 62 toises, or 360 feet, be found to be at a foot and a half or two feet, its greatest elevation above the line of level. From thence drawn to the earth by that gravitation to which all bodies are subject, it again inclines to the former line, and at the distance of about 120 toises, cuts it a second time. It is this second point of intersection which is called the musquet shot, or point blank, after which the bullet diminishes its paraHra to the end of its fall. What is here said is a common property to all arms.

It follows, that to make the ball arrive at the mark intended, the fire must not be always precisely levelled at that mark. Suppose a mark six feet high, divided into three equal parts, if the distance from it is 50 or 60 toises, or 360 feet, then to strike the upper dimension aim must be taken at the middle one, two feet under the mark. If meant to strike the middle, aim must be taken at the lower dimension, &c.

If at 100 toises, aim must be taken one foot below the mark in order to hit it. If the distance is more than 120 toises, to strike any of the dimensions, aim must be taken above the mark, and so keep raising in proportion to the distance.

Suppose a battalion of the enemy in front; if at 300 toises distance, aim should be taken three feet over the battalion. If at 200 toises, about a foot and a half. If at 150, aim should be taken at their hats. If at 100, at the middle of the body, &c. Although the horizontal shot of a musquet may be computed at 180 toises, yet, where the fire of a line of infantry can have effect, it is seldom more than 80 toises, or 460 yards.

I shall close this article with some account of the form of a review of a battalion of infantry, and the method of performing the eighteen manoeuvres, as practised by his majesty's forces.

**Reviewing the General.**

At the time appointed for the review, the battalion will, as directed above, draw up in open order. Four camp colours are to be placed to as to form a square, round the angles of which the wheelings are to be made. A fifth camp colour is to be placed eighty or a hundred paces in front of the centre of the battalion, where the general is supposed to take his station; and a sixth at the time distance, in the rear of the battalion, and opposite to the one in the front; but although the general may choose to quit that position, still the colour is to be considered as the point to which all movements and formations are relative. The colour must beropped, that the right flank of the division, when marching pull in review, shall be about four yards distant from the general.

When the reviewing general is within fifty or sixty paces of the centre, he will be received with a general salute of the colonel, with his back to the regiment, gives the word **present arms.** The men present arms, and the officers salute: the music will play, and the drums beat. The officers, in filing, take their time from the flag man; as he comes to the **Joise,** they bring their swords to the **receiver,** as he sinks his firelock to the left motion of the **present,** they drop the points of their swords; when he comes to the fifth officer, they bring their swords to the **receiver,** and then, taking their time from the colonel, bring them precisely under their bodies to the point, and remain perfectly steady and square to the front. The colours only salute such persons, as from their rank, and by regulation, are entitled to it.

The colonel then gives the word **shoulder arms.** While the general is going round the battalion, every person remains perfectly steady: no compliment is paid. The music will play, and the drums beat, but they will cease as soon as the general has returned to the right flank of the battalion. While the general is proceeding to place himself in the front, the colonel turns to the regiment, and gives the word **rear ranks take left ord.—march.** He will then, as also the lieutenant-colonel, mount on horseback in the rear of the centre, giving the words **companies, on the left back wards order. quick march.** Pioneers and music are ordered to the head of the column. Officers commanding companies must be very attentive when they give the words **halt.—drill,** to see that they are well obeyed.

**Column.—March.** The companies wheel successively at the front and second angles of the ground. When the leading company has made the second wheel, it brings them on the line on which they pass the general. Each leader of a company, when he has advanced fix paces from the wheeling point, changes quickly by the rear to the right flank of his company, and gives the words **eyes right,** thence **rear ranks take open order.** The music begins to play, the officers move three paces in front of the company, dividing the ground equally, the captain on the right, the lieutenant on the left, and the ensign in the centre. The captain's place is supplied on the right flank by his covering fireman, who is responsible for keeping the company at the proper wheeling distance from the one preceding it. The colonel is at the head of the general, or leading company, with the major a little behind him on his left. The music are in two ranks, six pieces before the colonel. The pioneers are in two ranks, six pieces before the music, having a corporal on their head to lead them. The drummers and fifers are on the left flank of their respective companies, and the supernumerary fifers three paces in the rear of their several divisions. The lieutenant-colonel is in the rear of the right company, the adjutant a little behind him on his left. The colours are three.
three paces behind the fourth battalion company, covered by
their ferrjeants. Staff officers do not march palt.

The officers, when within fix paces of the general, prepare
to salute, by recovering their swords. They drop them
when in a line with the general, and recover them when ten
paces from him, bringing them afterwards to the port, with-out
in the least altering the rate of march, or impeding the
front ranks of their companies. The commanding officer,
when he has saluted at the head of the column, places him-\self near the general, and remains there till the rear has
marched palt. The drummers give a roll each, when the
officers of their own companies salute. The officers of the
commanding companies will each successively, when he has
passed the general by thirty paces, give the words rear ranks,
take close order, and will immediately shift to the left, the
proper pivot. Officers bring their swords to the advance,
and each individual of the company refurns the port which
he held when the column was first put in motion.

When the third wheel is completed by all the compa-

dies, and the leading company is near to where the left of
the battalion stood in its original position, the colonel gives
the word halt. The whole halt, and the mufie ceaules, At the words support arms—quick march, the whole march

The colonel makes several wheels; viz. at the point where the left of the batta-

When the head of the column approaches to the left
of the ground on which it originally stood, the mufie will cease. The

When at the point on the left of the alignment, each officer gives the words halt, left wheel, halt dress, march. It is

When the line is formed, the colonel then cautions the
battalion, that it will perform the manual and platoon exer-
cises. He immediately goes to the rear, and the major, ad-

rear ranks take open order, march—order arms—wnts baysmets—
shoulder arms—officers take port in the rear. The officers
receive their swords, and face to the right. On the word
march, they, as well as the colours, etc. march through the
several intervals occupied by the ferrjeants, three paces beyond
the rear rank. At the word front, they face about, and
bring their swords to the port. The colonel, lieutenant colonel,
adjutant, ferrjeants, mufie, supernumerary ferrjeants, drummers
and fifers, are at their posts in the rear, as when the battalion
is formed at close order, where they remain per-
fectly ready.
The major proceeds with the manual as directed by regu-
lation. Obeying only the front rank comes down to the
left position of the charge baysmets, the others remaining
posted. The ferrjeants who pre-feze in the front rank the
places of the platoon officers, remain tlee freely during the
whole of the manual, except that they charge their pikes at
the same time as the baysmets. When the manual is over,
the major gives the words rear ranks take close order, march,
on which officers, ferrjeants, colours, and every other individ-
ual, take their places as when the battalion is at close order.
The major then gives the word platoon exercise, and proceeds
with it, according to regulation. When finif-ched, the major
goes to his post, the colonel comes into the front, and gives
the word with cartridge—prime and lead. The corps is now
ready to commence the selected motion. The flagel
man stands opposite the centre of the battalion, with his
back to the general, and goes through the motions as directed for
the manual exercise, etc. Of course he is not to per-
form any of what are called the flangle motions.

Method of performing the Eighteen Maneuvres.

First Maneuvre. Close Column on a Rear Division.
The colonel gives the word the battalion will form close
column of companies, in rear of the grenadiers. Remaining compa-

dies—right, face. All the companies, except the grena-
diers, face to the right. The captains and their covering
ferrjeants put themselves at the head of their files, ready to
lead. Two or three leading files of each company disengage
a little to the right. The captain of the grenadier company,
with his covering ferrjeant, shifts to the left of his company,
the pivot flank. The colonel then gives the word quick
march. All the companies, except the grenadiers, slip off
at once, and till the on in file till they come near the com-

The chief column of the fifth company halts one pace in
the rear of the covering ferrjeant of the grenadier company,
carefully covering him, and standing perfectly square in his
own person. His own captain also halts close to him, and
allows his company to move on in the rear of the ferrjeant,
taking care that the right hand, or leading file of the com-
paany, does not pass beyond, but mark time when it comes
up to the right hand file of the grenadiers. As soon, there-
fore, as the captain sees that the left hand file of his com-
paany is in with his covering ferrjeant, he instantly gives the
word halt, front, eyes left; and having dismissed his company

The clofe column being now formed, with the right in
front, the colonel gives the word, form column of grand
divisions.
diplomas. At this caution, all supernumeraries, but not the colours, go to the rear of the columns, not there already. Left companies, left face. The left companies immediately face, always to the pivot flank, and their captains take one file deep to the right, so as to be clear of their rank. At the word march, the captain flanks fall, the sergeants conduct the division, and the captain of each, when he has cleared the flanking division, gives the word batt. front, deft. He then steps numbly to the third file of the flanking company, and from that gives the word march, batt, deft. The captains commanding the right companies are now on the right of each grand division. The captains commanding the left companies move to the left flanks of the grand division, their intervals being kept by their serjeants. The colonel now gives the word, the column will close to the front, march. All the divisions step off, except the front one, and each, when within one pace of the division in its front, gets the word batt, deft, from the pivot captain of each division. The close column of grand divisions is now formed, and ready to deploy. The colours are with their proper division in the column, and that division must, of course, out-flank on the hand, not the pivot. To obviate this inconvenience, some regiments leave a space between the third and fourth grand divisions, for the colours.

The colonel then gives the word, the column will take ground to the right, and on its march deploy on the rear grand division. At this caution, a serjeant immediately steps out from the rear division, and places himself on the pivot flank of the front grand division, following it in file. When the rear grand division is halted, this serjeant halts also, and instantly fronts, remaining perfectly steady to mark the ground for the rear grand division to march up to. The colonel gives the word right face, quick march, and when the column, in obedience to these orders, has marched as far as he fees necessary, generally twenty or thirty paces, he gives the word rear grand division, batt, front, and when he feels that the division immediately before the rear one has cleared its front, he gives the word, fourth grand division, batt, front. As soon as the rear division, which has halted and fronted, finds its flank free by the batt, front, of the division that was immediately before it, at that instant the captain on the left gives it the word march. The grand division marches readily till it places its pivot flank; the left, to the serjeant, who had stepped out to mark the ground for it. Then it receives the word batt, deft, from the captain on the left. He draws his grand division, from the flanking serjeant (the point of appui) to the camp colour (the point of formation) on the right. As soon as the deploying is finished, he shifts to the right of his company. The rear grand division being dreeled, the fourth is marched up, and dreeled on it, exactly as the rear one had dreeled on the flanking serjeant, and the third, second, and first, till all are in line. If the deployment be correctly made, the first grand division has only to batt, front, as it is already in the true line. Much of the exactness of this, and every deployment of the same kind, must depend on the accuracy of the mounted officer, who halts and fronts each grand division. For this purpose he must be in the rear of the column. If he is confounded all will be deranged. Supernumerary officers and serjeants, drums, music, and pioneers, halt with their respective grand divisions, and as they are halted and dreeled, take their proper stations in the rear. The line is now formed to the general’s left.

Observe, when the column deploys on the rear division, it faces from the pivot flank, which then becomes the following one.

SECOND MANOEUVRE.—Close Column on a Front Division.

The colonel gives the word, the battalion will form close column of companies in front of the right infantry; remaining companies—left, face. The captains and their covering serjeants post themselves at the head of their leading files. Heads of files engage. At the word quick—march, the covering serjeant of the right company files briskly forward till he comes in front of the right infantry captain, and three paces from him he faces him. Then, being certain that he is in a true line with him, he immediately faces to the right about, and stands perfectly steady, and square to his front. The captain of the right company leads on his company till he places his pivot man close to the serjeant. He then gives the word batt, front, deft, replaces his serjeant (who immediately covers him), and gives the word eyes front. In this manner, each succeeding company proceeds, till the column is completely formed, with the prendrers in front. The colours move in rear of the fifth company.

The column of grand divisions is then formed, and closed up exactly as directed in the first manoeuvre.

The colonel then gives the words, the column will take ground to the left, and on its march deploy on the front grand division, left, face—quick, march. When the column has marched thirty or forty paces, or as many paces as the colonel fees necessary, he gives successively, and in due time, to each grand division the words batt, front, till all are halted, beginning with the front division. The inward captain of each grand division (that is, the captain on the right,) when it has halted and fronted, gives his words, deft, march, batt, deft, and the outward captain (the captain on the left) remains on the flank of the division in the line, till the succeeding captain, having so dreeled his grand division, comes to replace him. He then replaces his covering serjeant on the right of his proper company. In this manner, grand division after grand division comes up till the whole are in line, and the supernumeraries also take their places gradually in the rear.

Observe,—When the column deploys on a front division, it faces to the pivot flank, which then becomes the leading one.

THIRD MANOEUVRE.—Close Column on a central Division, facing to the Rear.

The colonel gives the word, the battalion will form close column on the right centre company, facing to the rear. Right centre company, right, face. Right counter-march, quick march. The captain at the head of his company, which has faced immediately on receiving the order, turns short to file to his right hand, and leads his company till he places his front rank in line with the rear rank of the fifth and third companies. He next gives the word batt, front, and then deft, from the right of his company, where he remains. The colours and centre serjeants counter-march with this company. At the word remaining companies, outwards face, the companies on the right of the right centre companies face to the right, thole on the left face to the left. Captains and their covering serjeants move to the heads of files. On the word to the left counter-march—quick march, the captains lead the files; the whole step off at once. The companies of the left wing, No. 5, 6, 7, 8, and light infantry, file one after another in the front of the right centre company. The right wing, No. 3, 2, 1, and grenadiers, file one after another into the rear of the right centre company. The serjeants must be very careful to follow the instructions, as in the first and second manoeuvre. Each company, as it completes its counter-march, receive the word, batt, front, deft.
The colonel gives the word *column march*. The column marches thirty or forty paces in its proper line. The adjutant having been apprized by the commanding officer, that the battalion is to change its direction to the left, and having the spot pointed out to him where the change is to commence, and also the direction which the column is to take, will immediately move forward, and place a camp colour at the spot where the leading company is to wheel. He will place a second colour as the point of direction on which the leading flank of the column is to move in the new alignment; and he will place a third camp colour, the point of formation, oblique to the right of the column, covering exactly the other two colours, so that a line drawn from the second colour to the first, and continued to the third, will be a right line, which line will be oblique to, and cut the original line on which the column was marching at the point where the leading company begins its wheel, which point is on the new alignment. These matters being all quickly arranged, when the colonel feels that the leading company is near the point of wheeling, he will give the words *wheel.*

The column will change its direction to the left. The captain of the leading company, on the principle of the movable pivot, gives the words *right shoulders forward,* and when the company has made the required wheel, he gives the word *forward,* and keeps his eyes fixed on the distant camp colour, to which he steadily marches. Each company, as it approaches the wheeling point, (the first camp colour,) conforms exactly to what has been done by the leading company. When the colonel sees as many companies wheeled into the new direction as he judges to be sufficient, generally three, he gives the word *halt.* The leading companies, and such others as have already wheeled into the alignment, being now at their proper points, remain so.

The rear companies will file into the new alignment. *Rear companies right, face.* At this word, all the companies who are right in the old direction face to the right, i.e. to the flank which conducts to their place in the new line. Captains and their covering serjeants shift to the heads of files, to lead them. At the word *quick march,* the serjeants step briskly forward, to mark their points in the line where the pivot flanks are to be placed. Each captain leads his company to his covering serjeant, where he halts, and lets his company pass in rear of the serjeant, till its left flank is in with him, and then he gives the word *halt.* When he gives the word *halt,* the serjeant of the right company moves quickly to the right, and places himself in line with the pivot. The rest of the covering serjeants go as usual to their right flanks, to keep the place for their captains. When the wheel is completed, the captains give the word *halt,* from the file on their right to the camp colour on the left, and immediately replace their covering serjeants.

**Fifth Manoeuvre.**—*Wheel thrown back.*

The colonel gives the following words of command; the *left company will wheel four paces backwards on its left.* The remaining companies will go to the right about, and wheel two paces to their right. The covering serjeant of the left company, now on the circle, wheels to the rear, and on the eighth file from the pivot marches the named number of paces, and comes to the right about, lining himself with the camp colour, placed by the adjutant on the right, to mark the new line, which is to be parallel to the original line of formation. The command is then given, *left company, four paces on the left backwards wheel, quick march.* The company’s serjeant halts the company in a low tone of voice, and the captain accurately drifts it on the colour to the right. At the
the word, remaining companies, to the right about face, they face accordingly. On that of, two pace to the right side, march, each covering serjeant steps out two wheeling paces on the circumference of the circle, and when the men wheel up to him, he halts them in a low tone of voice. The captain directs the company. The battalion now stands in echelon, with its rear ranks in front, the captains having shifted to the inner flanks of their several companies, and the rear covering serjeants to the outside flanks.

The battalion will march in echelon, and form line on the left company, march. The companies march with their rear rank in front. The captain of the company next to the left, gives the word left flankers forward, and then having directed himself from his own, the moment his leading flank man or his (now) front rank, touches the flank of the company that is already formed, he will give the word, but front, draw back on which his company fronts, and, without hurry, draws back on him and the formed part of the line, he correcting them on the more distant given point, the camp colour on the right, which having done, he goes to his post, the right of his company. Every other captain does the same, till the line is formed. It is then parallel to its original line of formation, but more retired by the length of four companies, supposing that three wheeled into the oblique alignment. The battalion is now to the general's left. It is to be observed, that the greatest activity must be used by each captain in this dressing, otherwise the point of appui will not be ready for the next company, and the distant point will be obscured; whereas it must be left open and distinct, so that the direction of the line may run at the distance of one file from the given object of dressing.

To follow the plan as laid down in the rules and regulations, the battalion should now go to the right about, retire fifty or sixty paces, and then halt, front.

Sixth Manoeuvre.—Counter-march, solid square, and change of position.

On the word, battalion, by companies on the left, backward wheel, quick march, the battalion breaks into open column of companies, the right in front. The colonel then gives the word, the column will change its front by the counter march of companies to the right, companies, right face. At this word, the whole face to the right. Each captain will immediately quit the pivot, and place himself on the right of his company, and his covering serjeant will advance to the spot which he has quitted, and face to the right about. At the word, right counter-march, quick march, the whole move. Each captain wheels short round to the right, and proceeds followed by his files of men till he has placed his pivot front rank man close to his serjeant, who remains immovable. Each captain instantly gives the words, halts, front, draws, to his company, so as to have it squared, and closed to the right, which is now the pivot flank. The captain replaces his serjeant, who falls back behind the rear rank. The column now stands to its former rear, with the left in front.

Column march. The column marches thirty or forty paces. At the word column will close to the front, the leading company immediately halts, and the remaining companies each halt within one pace of the company in its front. Captains must be very careful to halt draws their companies correctly, as this is preparatory to forming the solid square. Observe, that the column may be closed at the option of the chief, either in this manner, or by the head division continuing its march, and the rear ones being ordered to march quick into close column, and successively to resume the ordinary march.

Form solid square. All the companies composing the front half of the column, i.e. the left wing, take one pace forward, except the light infantry which stands left. The two left companies close up one and two paces to the company before them. At the word, solid formation, one pace to the right and left, march the whole companies make an interval of two paces in the centre, by their subdivisions taking each one pace to the flanks. Two captains, with their serjeants, place the serjeants on each of the front and rear intervals. Two captains, with their serjeants, also take post on each of the intervals in the centre of the files. A serjeant takes the place of each flank front rank man of the third division, and of each flank rear rank man of the last division. All the other officers, serjeants, the four displaced men, drummers, &c. assemble behind the centre of the companies which are to form the flank faces.

N. B. The remainder of this manœuvre cannot be correctly performed, unless each company consists of at least twelve files formed three deep.

Four files, outwards, face. The two rear companies face to the right about, and four files on each flank of all the companies, except the grenadiers and light infantry, face outwards, the whole lining with the flanks of the front company, and dressing in ranks from front to rear. On the word quick march, the fifth file from each flank of all the companies, except the first and left, followed by the front rank man of the sixth file, move up to right and left, and respectively fill up the interval between their own and the preceding division. The remainder of the men of the file divisions arrange themselves to their right and left, forming close in the rear of their own divisions respectively. The whole thus stand faced outwards, and formed in at least four deep, with two officers and their serjeants in the middle of each face to command. The captians may fill the intervals as follows: The grenadier and fifth company in the rear face; the light infantry and eighth company in the front face; second and third in the right face; fourth and fifth in the left face; each covered by his serjeant. All the other officers, as well as serjeants, displaced men, the colours, &c. are in the void space in the centre, behind their companies; and the files of the captains in the faces may be completed by serjeants, &c. from the interior, in such manner as the chief may direct. The mounted officers pass into the centre of the square by the rear face. Whatever is the strength of the companies which compose the flank files, the whole of them will face outwards, except their four centre files, which are always reserved for filling up the intervals.

Prepare for firing. The two fire ranks all round kneel, and slope their bayonets. The two next ranks fire flanking, and the others, if any, remain in reserve. The file covers behind each captain in the files give back, and enable the captains to stand in the third rank. They are replaced by their serjeants, who, with the serjeants in the angle, slope forward their pikes, at the same time that the men slope their bayonets. The colonel then gives the word command independent firing, and on the close of the preparative, the two flanking ranks commence file firing from the right of each face. This ceases on the beat of the general, and the colonel gives the word, kneeling ranks, present, fire. If ordered, the kneeling ranks may load again without rising up. Otherwise they immediately recover their feet after firing, and the word present and load is given.

When the colonel keeps it proper to reduce the square, he gives the words form close column. The files that faced outward, come to their proper front. Those in the intervals, i.e. the fifth file, and front rank man of the sixth, face about. At the word quick march, the front company takes one
one pace forward, and the two rear companies, i.e. the grenadiers and left company, one and two paces forward, and then face about. The files from the intervals take their proper places. Officers, serjeants, and men, &c. will quit the interior, move to their several flanks, and the companies that composed the flank faces will be completed. Now, if the word of command, the bait method to close the subdivisions, &c. is to move the column immediately, by giving the word, column, march, either in quick or ordinary time, as the colonel thinks proper.

When the column has marched as far as the commanding officer judges necessary, he gives the words, column will open from the rear, on which the captain commanding the rear company gives the word to his company, grenadiers, halt, and immediately the caution first company, to the company in his front. When he has exactly at a proper wheeling distance from him, he gives it the word halt. The captain of the first company, when he has halted, gives the same caution and command to the second; the second to the third, and so on in succession, till the column is opened out.

The colonel now gives the word, column will change its head by the counter-march of companies from the rear. Right swing, to the front. The grenadier captain gives the word, grenadiers, left face. He and his covering serjeant immediately swing to the left, and lead the files. He then gives the word halt, front, march (in ordinary time) close by the left flank of the first company. The captain of that company, while the other is approaching, gives the word, left, face; and as soon as the grenadiers have cleared his flank, quick march, leading his company into the rear of the now leading one. He gives the word halt, front, when he covers, and march, when at the due wheeling distance. All the other companies successively perform the same operation; and when the light company has taken its place in the rear, the whole column is in perfect order.

Column, halt, left wheel into line, quick, march. When the battalion has wheeled into line, it is considerably to the general's right, and with its rear to him. Observe, That some regiments at review, in this counter-march from the rear to the front, face their companies to the right, and bring them out on that side, contrary to the general principle. The divisions which advance come out always on the side to which front is to be made, and on which the enemy is placed; because then, with the divisions that are free, he can be opposed, while the others are moving behind the line.

Seventh Manoeuvre.—Counter-march by Files on the Centre of the Battalion.

This brings back the battalion to its original front. The colonel gives the following words; the battalion will counter-march from its centre, and on its centre, by files, swings, into place. The colonel faces his company into the line, remains to mark each flank of the battalion. The word is given, swings, three files to the right—march; if the battalion is only two deep, two paces to the right is sufficient. Each wing takes the named number of paces to its flank, that they may be difengaged from each other. At the second word march, or quick, march, the whole move on, and each file wheels successively into the centre, as it arrives at and beyond the colours. As soon as each company is in the line from the colour to the flank serjeant, the captain fronts it. When the whole is formed, the colours countermarch, and if necessary, the dressing of the line is corrected.

Battalion.

Eighth Manoeuvre.—March in open Column. The battalion will form open column in rear of the left company. Remaining companies on the right backwards wheel—quick march. All the companies wheel backwards on their right, except the right infantry, which fall in. On the word left face, they all face to the left, except the light company; and the captains place themselves to lead the files. At the word quick march, the whole will lead to the rear, and the covering serjeants will successively, as before, take up their points on the new line. The captain conducting each platoon, when he arrives at his serjeant, will stop directly before him, allow his platoon to move on behind the serjeant till the rear file comes close to, but beyond him. The captain will then halt, front, and desea his platoon, with his front rank closed in to the serjeant. He will himself take the place of the serjeant, and remain ready on the pivot flank.

As soon as the third company has taken its place in the column, the colonel gives the word march. The head of the column moves on in ordinary time, and the remaining companies follow, preferring the proper wheeling distance between each. When the leading companies arrive at the necessary points of the column, the colonel will give a loud caution, that the subdivisions are to double, either by companies successively, or the whole battalion at once. If at once, as is ordered in this manoeuvre, then he gives the words form column of subdivisions—right subdivisions—mark time. Each right hand subdivision marks time, till its left hand subdivision, which marches on steadily, has opened or cleared its flank. At the words quick oblique, or left oblique, the right divisions immediately oblique to the left, and cover the left ones correctly. The captains move to the right flank of the left subdivisions. Their covering serjeants lead the right subdivisions.

When the column of subdivisions has marched as many paces as the colonel deems proper, he gives the word form companies, right subdivisions—quick oblique. As soon as each right subdivision has cleared the right flanks of the left, by the quick oblique, it immediately receives the word forward, and when in line with the left subdivision, each receives the word ordinary from the captain, who had shifted to its right. It may be observed that the above is in conformity to the general rule, whether the column be halted or in motion, that the subdivision or section on the reverse flank is the one behind which the other subdivision or section doubles. But in this case, were the left subdivisions to double in front of the right ones, the pivots would be better discharged, as the right subdivisions, which were marching correctly in the alignment, would not be discomposed. The colonel gives the words column halt—right wheel into line—quick march.

Ninth Manoeuvre.—Echelon Change of Position.

The colonel gives the words, companies on the right backwards wheel—quick march. The battalion breaks into open column, the left in front, every company getting the halt—drifts from its own captain, as usual. The colonel commands; The seventh company (the third, reckoning from the left) will wheel four paces, the remaining companies fix places, on the left backwards—quick march. The companies are drefled by their captains, who are now on the infiles flanks of the echelon. The colonel orders right and light company right about face. Two camp colours are sent to the right and left in a correct line with the seventh company. At the word the column will march in echelon, and form line on the seventh company—march, the captain of the seventh company shifts to its right flank. Each company on the right of the seventh, viz. Nos. 6, 5, 4, 3, 2, 1, and grenadiers, as it comes successively into line, receives from its captain the word halt—drifts.
Battalion.

—dres on the camp colour to the right. The captain then shifts to the right of his company. The companies on the left of the seventh, viz. No. 5, and the light infantry, receive the words from their captains halts, fronts, dres up. They are dres on the camp colour to the left.

Tenth Manoeuvre.—Echelon Change of Position.

The colonel gives the words the light infantry will wheel four paces, the remaining companies two paces to the left. When the covering serjeants have taken the named number of paces from the front of the eighth file from the left of their companies, the colonel gives the word quick—march. The captain commanding the light infantry immediately shifts to its left flank. When the company has wheeled up, he gives the word halt, dres, dres it correctly on the camp colour, which the adjutant had previously sent to the right for this purpose. The captain, when his company is correctly dres, gives the word eyes front, and resumes his place on the right of his company, taking care that his men stand perfectly steady, and with carried arms, until the next company has dres on them; his right flank being the point of appui. When the colonel sees that every division is ready, he gives the words the battalion will march in echelon, and form line on the left company—march. All the companies march in ordinary time. As they arrive in line successively, they are dres by their captains from their standing companies to the camp colour on the right. Each captain, when he has so dres his company, gives the word eyes front, and then shifts to the right of his division. The whole are now formed in line, parallel to their original front, and considerably to the general's right.

Eleventh Manoeuvre.—Change of Position.

The colonel gives the words the battalion will form open column of companies in the march—right face—march. When the battalion has marched in file as far as is judged necessary, he gives the word form companies. The files instantly make a half face, each marching up quick and diagonally to their respective leading men, who do not alter their pace. As the pivots are in the rear of companies, when they come up, the companies dres to them by their captain giving the word eyes left; and they take up as they form, the ordinary step. The column marches; and when the colours are opposite to the general, the colonel gives the word halt, and then to the left wheel into line, quick march.

Twelfth Manoeuvre.—Retreat in Line.

The colonel gives the word the battalion will retire—right about face—march. It marches fifty or fifty paces in ordinary time dres by its centre. No music plays during the retreat of the battalion. The colonel gives the word halt front, and directly after the battalion will fire twice by companies, from centre to flanks. On the left stroke of the preparative, the captains on the right of companies step out one pace, and give the word of command platoon, ready—present—fire—load. When the first part of the general is beat, the captain falls back into the front rank. The colonel then gives the word, the battalion will retire by alternate companies—right companies, right about face—march. After marching in ordinary time about fifty paces, they receive the word halt, front. In marching, one colour remains on the flank of its proper company in each line. The King's colour with the right centre, and the other colour with the left centre company. A serjeant will advance six paces before each colour during the march. Each line directs its movements by its colour; distances are preferred from that colour, and to it the men's eyes are turned during the march. Each line has a commander. Captains are ordered to be on the inward flanks of their companies, but this makes a perpetual shifting of positions, and is better omitted.

The colonel gives the word left companies, make ready—present—fire. Immediately after firing, the men come to the recover, half cock, and shoulder arms. At the word right about face—march, the left companies march steadily on, dres by their colour. They pass through the intervals of the right companies, and continue marching until they receive the word from the colonel halt front—prize and load. If the chief fires the left companies, the next in command fires the right companies, exactly as the left companies were fired. They retire in the same manner through the intervals of the left companies. The colonel then fires the left companies, and retires them as before, and so on till he thinks it expedient to form line.

The left companies will form line on the right companies—march. When they have marched and filled up the intervals, the word halt is given by the colonel, and dres by the captain of each company. The right companies may form line on the left in the same manner. Sometimes the right companies are fired in battalion previous to their retiring. The words of command are the same as if they had been separated from the left companies. The light infantry may be divided in the intervals of the first line, retire with it, and charge to the other line, whenever it becomes the advanced one. In this situation, they cover the retreat, and may occasionally fire; and when the line is formed, they resume their pivot on the left. Unless, however, the battalion is very strong, the light infantry remain in their usual position as a company. When the line is formed, the colonel gives the word the battalion will retire in line—right about face—march. When it has retired as far as he chuses, he gives the word halt, front.

Thirteenth Manoeuvre.—March to a Flank in Echelon.

The colonel gives the word the battalion, by companies four paces to the right wheel, and form echelon. Covering serjeants take the named number of paces as usual. The pivots make a half face to the right, the serjeants dres by them. On the word quick march, captains on the right of their companies give the word halt, dres. Covering serjeants go to the reverse flank. The colonel then gives the word the battalion will advance in echelon—march. The whole advance to the flank in echelon about two hundred and fifty paces. At the word wheel back into line, the three centre serjeants instantly step out into the front, and mark the time for the battalion. The pivot mark time, gradually turning to their proper front, while the rest of the divisions wheel back the four paces they had advanced. When the fourth pace is completed, the colonel gives the word forward; and the whole, dres by the centre, step out their full pace, till they receive the word halt. The line is then considerably to the general's left, and parallel to its original front. In this situation, the colonel commands fire three roundly by companies from centre to flank. Each captain gives the words platoon, ready, present, fire, load.

Fourteenth Manoeuvre.—The Hollow Square, and its Movements.

The colonel gives the word the battalion will form a hollow square on the three centre companies (viz. the fourth, fifth, a sixth), remaining companies—four paces on the right and left backwheels wheel—quick march. The companies on the right each wheel back the eighth of the circle on their left, and the companies on the left wheel the same number of places backward on the right. The colours, at the same time that the companies are forming their echelons, move back, three paces into the rear. The fourth company by the side...
BATTALION.

The column then gives the words, in echelon, march, to form square—march. Two serjeants or camp colours should be placed in the rear, in a perpendicular line with the outside flanks of the front face, marking out a perfect square. The companies now march in echelon, and by the turning of the left shoulders of the right companies, and the right shoulders of the left companies, they wheel in to form square. Their captains halt and front them in a correct line. The first company will wheel round the serjeant placed to mark the angle, and the grenadiers round the proper right of the first company; the light infantry at the same time wheeling round the serjeant on the opposite angle, till their right flank touches that of the grenadiers. They then, as also the first company, get the words halt, front, drefs, from their captains. They have then formed the rear face of the square, and in this manner the proper front rank of the rear face will be outward. The square is now perfectly formed, and composed of four faces. The front face consists of the fourth, fifth, and sixth companies; the right face of the third and second; the left face of the seventh and eighth; and the rear face of the first company, the grenadiers, and light infantry. The mounted officers, colours, music, drummers, &c. and the battalion guns, are all within the square.

The colonel then gives the words the square will march by the right angle of the front face, left and rear faces—right about face. The two sides that form the right angle, that is, the front face and the right face, stand fall; the other two sides, viz. left face, and rear face, go to the right about. At the word by subdivisions, four faces to the right and left wheel—march, the whole by subdivisions wheel up one eighth of the circle, two sides to the right and two sides to the left, and are thus parallel to each other, and perpendicular to the direction in which they are to move. The pivot flanks are in this manner placed on the sides of the square, each side being thus in echelon, and the colours behind the leading angle. At the word march, captains, who are on the inward flank of their leading subdivisions, carefully preserve the distances they wheeled at, and from the flanks to which they wheeled. At the words halt, front square, or reform square, the whole wheel back into square; and the two sides that require it, that is, the left and rear faces, go to the right about. Captains dres their divisions as usual, in the same manner as is described for the square. The directions given for the march described, the right angle of the front face, will equally apply, should it be found necessary to march the square by any of its other angles.

The colonel then gives the words the square will march by the right face. The colours move up behind the centre of the named face, as do the mounted officers, &c. At the word front and rear faces, by subdivisions to the right and left wheel—quick march, the opposite side, that is, the left face, faces about; and the two flank sides wheel up by subdivisions, so as to flank each in open column. At the word by right face—march, the square marches two sides in line and by their centre, and two sides in open column, which cover and dres to their inward flanks on which they wheeled up carefully preferring their distances. The same directions that are given for marching by the right face, will apply to the march by any of the other faces. The colonel, when the square has marched as far as he sees necessary, gives the word halt, reform square. The square halts, the subdivisions in column immediately wheel back, and form their sides, and the side which faced about again faces outward. The captains give the words halt, dres.

On the word prepare for firing, the front rank kneel and present their bayonets sloped. The square is then ordered to fire in whatever manner may be judged proper; the two rear ranks to fire standing; or companies by ranks successively; or by companies independent of each other; or by subdivisions, one firing when the other has loaded; or companies by files; as ordered. The front rank remains as a referee. Should the battalion be formed only two deep, the front rank will remain kneeling, and the other rank will fire by files. The word is now given square will fire by companies, beginning on the right. When the firing by companies has ceased, the command is given by the colonel kneeling ranks, make ready, present, fire (the men rise up after firing), prime and load. The word is then given the square will form line on the three centre companies—side and rear faces—by companies, for faces to the right and left wheel, quick march. The captains, as usual, halt—dres their companies. The words are then given in echelon march and form line, march. The whole march in echelon, except the three centre companies, the outward companies taking care not to impede the inner ones, which must form before them. This may be done by the facing and filing of each division from its inward flank to its point in the new line, where it will form up. Captains halt—dres their companies, as in the third manœuvre.

If the square is composed of the eight battalion companies only, then the grenadier and light company may be placed as a referee in the rear, ready to be applied according to circumstances. In marching the square by any of its faces, some regiments have been instructed to march two sides in file instead of open column; and if the men march tolerably in file, there can be no question but that it is the best method.

FIFTEENTH MANOEUVRE.—Retiring and filing to the Rear.

When the battalion is to retire, it ought to be previously dresed with the same exactness as when it is to advance, and the same care in ascertaining the direction of its march must be taken. Therefore, before the retreat is to begin, an officer or serjeant will have placed himself thirty paces in the rear, so as to stand perpendicular to the front directing serjeant; and of course he will be in the line, or nearly so, of the directing serjeant. Whenever the battalion marches to the rear, it must cover its proper extent of ground. The rear must therefore avoid closing their files more than usually. In some cases, the front rank men, who are in general larger, will be crowded in their rank. Music, drummers, supernumerary officers, &c. will take care to march with exactness, and not to interrupt, but rather assist the battalion.

The colonel gives the words the battalion will retire. As soon as this caution is given, the three directing serjeants face about. The same centre serjeant that directs to the front, directs also to the rear. He moves on in the line of the advanced officer, six paces beyond the rear rank, and halts. The two other serjeants move up on each side of him. When the line is retiring, music is never to play. On the word right about faces, the whole face; and the supernumerary officer, who had replaced the directing serjeant, moves up into the leading rank. A mounted field officer passes through to the rear, and the directing serjeant in the interior prolongs his line, and takes his object between the feet of the polled officer. Immediately after facing about the word march is given by the colonel. The whole battalion instantly sets off. The replacing officer between the colours prefers, during the movement, his exact distance
of six paces from the advanced ferjeant, and is the guide of the Battalion, the directing ferjeant conducting on his points under the correction of the colonel, who is ten or twelve paces behind the centre of the battalion. In this retreat, if the light infantry act separate, and not as a company of the battalion, at the word march they move quickly round by the flanks, and form in the rear of the centre, extending far to cover it during the retreat, and following at the distance of fifty or sixty paces.

The colonel gives the word: the battalion will, from the proper right of companies, file to the rear—pass companies by files. Each captain instantaneously gives the word left, turn—quick march, and wheels out his leading file, the rest of the files following in succession. The heads of companies must observe the proper distance from each other, and are regulated from the left. Circumstances may require that the companies should pass from their proper left, instead of the right, in which case the leaders will shift and conduct such left until the line is formed, when they will again resume their proper places. When the companies in files have marched as far as is necessary, the colonel gives the word halt, front. The whole now stand in open column of companies, the right in front. When the column is ordered to halt, the light infantry passes quickly through it, and takes post thirty paces in the rear of the intended line. On the word by companies, left, wheel into line—quick march, captains, as usual, halt, dress their companies. When the line is formed, its centre is opposite to the general.

Sixteenth Manoeuvre.—Filing, advancing, and charging to the Front.

The colonel, having previously placed himself ten or twelve paces behind the exact line of the directing ferjeant, will remark the line of its prolongation, and thus ascertain the direction in which it should march, and in doing this, he will not at once look out for a distant object, but will hit on it by prolonging the line, from the perilon of the directing ferjeant to the front. Or he will order the covering ferjeant to run out twenty paces, and will place him in the line in which he thinks the battalion ought to advance. The directing ferjeant then takes his direction along the line which passes from himself, betwixt the heels of the advanced ferjeants, and remarking the object, proceeds with twice the line in advancing. The colonel then gives the words the battalion will advance. Before the line so advances, the light company quickly forms, in extended order, thirty paces before the centre, and prefers that distance in advancing. The front directing ferjeant of the battalion moves fix accurate and exact paces in ordinary time, and halts. The two other ferjeants that were behind him, move up on each side of him, and an officer from the rear replaces in the front rank the leading ferjeant. The centre ferjeant, in moving out, marches and halts on his own observed point, and the two other ferjeants dress and square themselves exactly by him. The directing ferjeant, after being assured that he himself is perfectly and squarely placed in the rank, by calling his eyes down the centre of his body, from the junction of his two heels, and by repeated trials to take up or prolong a line perpendicular to himself and to the battalion, will observe and take up any accidental small spot on the ground, and within 100 or 150 paces, intermediate ones cannot be wanting, nor the renewal of such as he afterwards successively approaches to in his march. In this manner he is prepared, under the future correction of the colonel from behind, to conduct the march.

The line of direction being thus ascertained, the colonel gives the word march. The whole instantaneously step off, and without turning the head, eyes are glanced towards the colours in the front rank. The replacing officer between the colours preserves, during the movement, the exact distance of six paces from the advanced ferjeant, and is the guide of the battalion. The centre advanced ferjeant is answerable for the direction, and the equal cadence or length of step. To these objects he alone attends, while the other two, fervently conforming to his position, maintain their parallelism to the front of the battalion, and thereby present an object to which it ought to move square. They are to allow no other consideration to attract their attention, and will notice and conform to the direction of the commander only. If any small alteration in their position is ordered, it must be gradually and coolly made. When the battalion is advancing in line for any considerable distance, the music may be allowed at intervals to play for a few seconds only, and the drums in two divisions to roll; but it is the wind instruments only which play. The large drum, or any other instrument whatever, which marks time by the stroke, is not permitted.

When the battalion advances fifty paces, the colonel gives the words the battalion will file from the right of companies—paix files to the front. Each captain immediately gives the word right, turn—quick march, wheels out his leading file, and passes on direct to the front, preferring a relative distance from the left, as being the head of the column, or from the other flank, if particularly so ordered. When the column has marched fifty paces, the colonel gives the words halt, front. The whole now stands in open column, the left in front. The light company passes quick to the rear, assembles half of it behind each flank, and moves relatively with the flank companies.

The words now given in succession are columns, right, wheel into line, quick, march. The battalion will advance—march. The battalion marches fifty paces. The battalion will advance by alternate wings, and fire four times—left wing, halt. The left wing halts, and the right wing continues to move on fifteen paces. Left wing, march. Left wing, halt, ready, present, fire, load, march. The left wing marches past them till the right wing, being loaded and shouldered, receives the order to march. Left wing—halt, ready, &c. as directed for the right wing, and thus they alternately proceed, till each wing has fired twice. The left wing will form line on the right—right wing, halt. When the line is formed, the battalion will advance, march. After marching fifty paces, halt. The battalion will fire a volley—front rank kneeling, make ready, present, fire, prime and load. The battalion will advance—march. When it has advanced twenty paces, it receives the command halt. The battalion will fire a volley—front rank standing, present, fire, prime and load. The battalion will advance—march. When it has advanced fifty paces, halt; the front rank comes down to the charging position. Shoulder arms—prime and load. The light company, lying down behind the flanks, pursues, return, and assemble and join on the left of the battalion. The battalion is now advanced near the general, and with its centre opposite him.

If the battalion is not very strong, the light infantry should not act as such, but only as a company in battalion. In firing by wings, that is, by half battalions, the colonel generally fires the right wing, and the next in command the left. When the battalion has charged bayonets, they may be ordered to move forward on the charge at a very quick step; but by no means to run. A very few paces only can be necessary. Care must be taken that the battalion moves in perfect dress, which it cannot do if it run. The flugel man gives the time for each wing to call about, and shoulder.
BATTLE.

SEVENTEENTH MANOEUVRE.—Retiring in Line.

The colonel gives the words the battalion will retire—right about, face—march. While it is retiring, he gives the signal the battalion will fire twice; by alternate wings—the two left ranks, flanking. He then gives the words right wing—halts, from. The light infantry are not ordered by the rules and regulations for the infantry formation, to cover the right flank of the regiment; but it appearing to be as requisite as in advancing, they will be formed separately. On the halt of the right wing, they file round the left flank, and cover the left wing at six paces in front, firing and retreating till they occupy the ground quitted by the left wing, dresling by the right. When the left wing has gained fifteen paces, it receives the word from the lieutenant-colonel, halts, front. The light infantry cease firing. The colonel orders right wing—ready, present, fire (the men after firing immediately come to the port, or to the recover, as may be ordered). The light infantry face to the right, and cover the right wing at six paces. On the words right about, face—march, the light infantry fire retiring, till they come into line with the left wing by which they dres, and continue firing. When the right wing has marched fifteen paces beyond the left, it receives the words, halts, from—prime and load. When loaded, the signal founds for the light infantry to cease firing. The infant receives the colours of the right wing has fronted, he immediately gives the word of command, which conforms in every particular to what the right wing has done. The light infantry face to the left, and cover the left wing as they did the right, dresling by the right. In this manner each wing alternately proceeds, every due dispatch being made in reloading. When the wings have each fired twice, the colonel gives the words the left wing will form line on the right wing—march, halts, front—prime and load. When loaded, the light infantry ceases firing, and the signal is given by the bugle for it to form company in the rear of the centre. The colonel gives the word the line will retire; and when it has marched a hundred paces or more, covered by the light infantry, who file round the flanks, halts, from. The light infantry, upon signal, form company in the rear of the centre and afterwards resume their post on the left of the battalion.

In retiring by alternate wings, one colour remains on the inward flank of each half battalion, to which the men continue to look when they move, by which they dres, and before which a directing sergeant advances six paces. The make ready—present—fire of the advanced wing is instantly to succeed the march of the other advancing wing or the halt, front, of the retiring one. In the half battalion firing, advancing, and retreating, if formed two deep, both ranks will fire flanking. If formed three deep, the front and centre ranks will fire flanking, and the rear rank will remain shoulder in reserve.

EIGHTEENTH MANOEUVRE.—Advancing in Line.

The colonel gives the word the battalion will advance—march. It marches a hundred paces, and receives the halt. At the words fire a volley obliquely to the right, the men of the front rank turn one-eighth of a circle to the right; those of the rear ranks take a pace to the left, and cover their proper file leaders. The words are then given make ready, present, fire, load. Fire a volley obliquely to the left—make ready, present, fire, load (the ranks execute the reverse of what is directed in the firing to the right). The battalion will advance—march. When it has advanced a hundred paces, halt. Fire two volleys to the front—after the left, the men will port arms, and half cock. Battalion—ready, present, fire, load. Battalion—ready, present, fire, load. Shoulder arms—front paces—rear ranks, take open order—march. The colonel and lieutenant-colonel now dismount, and come through the centre into the front, as do the nuice. Every one takes his station exactly as they had been placed when receiving the general. The colonel, with his back to the regiment, gives the words the battalion will advance—march. The nuice plays, and when the line has advanced within fifty paces of the general, the colonel gives the words halt—general salute—present arms. The nuice plays God save the King, and the drummers beat a march. When the nuice ceases, the colonel, turning the battalion, gives the words shoulder arms—rear ranks, take close order—march, and the review is ended.

Light infantry. The following is the method usually observed by the light infantry when required to form in extended order, as commenced at the twelfth manœuvre. Previous to the retreat in line, the colonel directs the horn to sound the signal for their forming company, when the officer commanding it gives the words right face—quick march (in double quick time, to ten paces in the rear of the supernumerary rank, its centre covering the colours)—halts, front—order arms—unfix bayonets—form two deep (the left subdvision of the rear rank steps back one pace) rear rank to the left face—quick march (its left subdivision arrives between it and the centre rank, when the whole moves forward)—halts, front, dres, is then given by the senior supernumerary officer. The light infantry being divided into subdivisions, the right is commanded by the captain, and led by his covering sergeant; the left by the senior lieutenant, and led by the second sergeant; the second lieutenant attends the right subdivision. On the retreat of the line, at signal from the horn, the subdivisions face outward, and file, in quick time, round the flanks of the line, forming (when the retreat is made by alternate companies) at ten paces in front. The right subdivision covering at equal distance the right wing, except the grenadiers, and the other the left wing in the same manner, dresling to the centre. When the word march is given to the line, the light company, at the sound of the bugle, commence firing for the left round from centre to flanks. Each man, when he has fired, retires the ordered number of paces, generally four, by the left of his file, commands, and reloads. On the fronting of the battalion, they form companies as before mentioned, round the flanks, in rear of the line, where they divide into fections. The two fections of the right subdivision form in rear of the first and third companies those of the left in the rear of the fifth and seventh. All the fections are faced to the left, and on the retreat of the alternate companies, suppose the left move instantly into the intervals, and form as much extended as is necessary, in line with the right companies, who still remain stationary, firing independently till the companies in line receive the order to make ready. When the right companies retreat, the light infantry move to the right, cover them as they had before done the left, and fire retiring till they arrive at the intervals between the left companies, upon whom they dres. Thus they alternately continue to occupy the intervals, till the line being formed, they wheel round the respective flanks, form subdivisions in rear of the second and seventh companies, form again in front on the retreat of the whole line, in extended order, and at its halt, assemble again in company behind the centre. In advancing in line, and by wings, the movements are similar to those already explained in the seventeenth manœuvre, with this difference, that the company moves forward instead of retiring. To re-form three deep, when re-assembled in company behind the centre of the line, the officer gives the words form three deep (the third fection, or the whole of the proper rear rank, steps back one pace) rear ranks, to the right face—quick march (the right—present—fire, load. The words are then given make ready, present, fire, load. Fire a volley obliquely to the left—make ready, present, fire, load (the ranks execute the reverse of what is directed in the firing to the right). The battalion will advance—march. When it has advanced a hundred paces, halt. Fire two volleys to the front—after the left, the men will port arms, and half cock. Battalion—ready, present, fire, load.
rear rank of the section marks time till the front rank has passed it, and then moves on.) At the word halt, front, they cover the centre rank correctly, at one pace distant from it. The company then fixes bayonets, faces to the left and resumes the proper position in line.

Observations.

The number of paces mentioned in the several movements are not to be positively prescribed, but are supposed to be nearly such as will give the intended relative situations. If the ground allows the marches to the rear and front to be longer, it will be so much the better.

The colonel should give all his commands from the rear of the battalion. No commanding officer should attempt, in the face of the general, to put the regiment through any of the maneuvers without being himself perfectly and minutely acquainted with the principles on which each is performed. He will thus avoid the disgrace of calling to his adjutant for instruction, or galloping full speed to the flank of the battalion by way of rectifying a mistake which his ignorance and temerity have brought him into, and which he cannot remedy but by recurring for advice either to the other mounted officers, or to the sergeant-major in the rear.

When the reviewing general has seen the battalion go through each of the ordered manoeuvres as he judges necessary, he will, that he may be able to report on the merits of its performance, among other circumstances, particularly observe and specify, whether or not the original formation of the battalion is according to orders.

The marches are made with accuracy, at the required time and length of step, and on such objects as are given. The proper distances in column and echelon are at all times preferred. The wheelings are made just, and in the manner prescribed. The formations in line are made true, without false openings, or necessity of correction. The officers are alert in their changes of situation, exact in their own personal movements, and loud, decided, and pointed in their words of command. The march in line is uniformly steady, without floating, opening, or closing. The march in file close, firm, and without lengthening out. The officers and supernumeraries give the aids required of them with due quickness and precision. Hurry and unnecessary delay in the movements are equally to be avoided. In the firings, the loading is quick, the levelling just, the officers animated and exact in their commands.

Form of finding for, and lodging the colours. The battalion being in line, the commanding officer orders the grenadier drummers to beat the drummer’s call; on which the two youngest ensigns recover their swords, face to the right, and march between the line of officers and the front rank, till they come to the head of the grenadiers, where they halt, front, and bring their swords to the port. The drum-major, with a party of drummers and fifers, will likewise face to the right, and march to the head of the grenadiers, placing themselves between the ensigns and the front rank. The grenadier captain then makes his company take close order, and will either wheel them by subdivisions, or march them in one file. If by subdivisions, he places himself on the pivot flank of the file, the eldest lieutenant on that of the second, and the other lieutenant in the supernumerary rank of the file; but if the company is marched in one division, the two lieutenants are in the supernumerary rank. The company then marches, in ordinary time, to the quarters where the colours are lodged, when it halts, and rear ranks take open order. The drum-major unfurls the colours, and gives them out of a window to the ensigns, who on halting had sheathed their swords. The captain then orders his men to present arms. Officers salute, and the drummers beat a point of war, which finished, he shoulders arms, cloths the ranks, and marches them off in ordinary time, the drummers beating the grenadier’s march. On arriving at the left flank of the regiment, the company faces to the right, the ensigns with the colours march in front of the line of officers, the grenadier officers between them and the front rank, as also the drums and fifes, and the grenadiers in files, between the other ranks. The commanding officer of the regiment, as soon as the colours arrive on the left flank, orders the battalion to present arms, the officers salute; the fifes play God save the king, and the drummers beat the troop. On the colours arriving in the centre of the battalion, the ensign halts and fronts, and, when the grenadiers have taken post on the right, the battalion is ordered to shoulder arms.

When the colours are to be lodged, on the drummer’s call being beat, the ensigns, the drum-major, and a party of drummers and fifers, march and take post in the front of the grenadiers. The battalion presents arms, officers salute, music plays, and drums beat. On the captain of grenadiers marching off with the colours, drummers beat the troop. When they arrive at the house, or place where they are to be lodged, the drum-major receives them at a window, the grenadiers present arms, officers salute, and drummers beat a point of war. The ensigns on quitting the colours, draw their swords, and salute with the other officers. The captain will either march his company back, or dismiss them, as he may be ordered by the commanding officer.

When the colours are not to be received, or lodged in form, the sergeant-major, with four sergeants in the centre of the battalion, will take the colours called, from, or to the place where they are kept, in the following manner. Sergeant-major, the two front rank serjeants carrying the colours on their shoulders, covered in the rear by two other serjeants and the drum-major, is to receive them when they arrive at the place of their destination. No compliment is paid by the battalion in this cafe, and they are generally set away when the ranks are closed. When the regiment is ordered for a field day, the colours should never be received or lodged in form, as it takes up too much time.

The following is at present the detail of the battalion. Field officers—one colonel, one lieutenant-colonel, one major, (by a late regulation field officers have no companies,) ten captains, twelve lieutenants, and eight ensigns. There is no captain-lieutenant. Staff officers—one adjutant, one pay-master, one quarter-master, one surgeon, one adjutant-surgeon. Non-commissioned officers—one serjeant-major, one serjeant-major, thirty serjeants, thirty corporals. Drums—one drum-major, twenty-one drummers and fifers. Privates—five hundred and seventy.

Rules and regulations for his Majesty’s forces. Ruffell’s Instructions for the Drill, London, 1803, &c. &c.

BATTARDEAUX, in bridge-building. See Cofferdams.

BATTATA, in Botany. See Dioscorea.

BATTATAS. See Helianthus.

BATTAWAY, in Geography, a town of Africa, on the Grain Coast, as far known at sea by two large rocks, two miles distant from the shore to the west, and also by some high mountains behind the town. This is one of the best built places on the coast; populous and rich, and trade extensively in pepper and ivory. The people however are addicted to thieving.

BATTLE. See Bataile.

BATTLES, in Geography, Law &c. See Battle.

BATTEN, in Carpentry, a name which the workmen give to a scantling of wooden stuff from two to four inches broad, and
and about an inch thick; the length being pretty consider-able, but undetermined.

The term is chiefly used in speaking of doors, &c. which are not framed of whole deal, &c. with files, rails, and pan-nels like wainscot, but are made to appear as if they were, by means of these pieces, or battens, bradded on the plain board round the edges, and sometimes crofs them, and up and down.

Hence batten doors, or windows, are such as feem to be wainscot ones, but are not. There are faid to be either fingle or double, as the battens are fitted on to one fide, or to both.

BATTENS of the hatches, in Sea-language, are nailed along the tarpaulings, and ferve to keep their edges close down to the hatches, in order to prevent the water which wafhes over the deck from penetrating into the lower apartments of the ship.

BATTEN, in Geography, a town of Germany, in the circle of the Upper Rhine, and principality of Upper Hesse; 16 miles south west of Waldeck, and 16 north west of Marburg.

BATTENBURG. See Batenburg.

BATTEN Kill, a small river of America, which rises in Vermont, and after running north and north-westward about 30 miles, falls into Hudson, near Saratoga.

BATTERBURY, or Batterby bay, lies on the west coast of Ireland, about two miles north east from Connit islands. It has a narrow entrance, but is above 4 miles broad. N. lat. 53° 19'. W. long. 10° 22'.

BATTERIE, a French term in Music, for that kind of arpeggio, or breaking of chords in a distinct and detached manner, different from common arpeggios, in the execution of which on keyed-instruments, no finger is taken off till the note assigned it is again wanted; and when, on the violin, the notes of a chord are not, as usual, swept up and down in one bow, but either all to be bowed or separated by a tremulous motion of the bow.

In this article of the Encyc. Meth. after the definition of the term Batterie, and a necessary addition by M. Framery, are inserted, the Abbé Peyton takes the pen, and in treating the subject metaphorically, manifests deep reflexion and science in the theory of sound; but with a total disregard to the præcife of the greatest composers and performers, who have produced pleasing effects by the very means which he prohibits.

BATTERING-RAM. See Aries.

BATTERING-Ram, in Heraldry, a bearing or coat of arms reembling the military engine of the same name.

Battering, the attacking a place, work, or the like, with heavy artillery. See Battery.

To Batter in Breach, battre en breche, is to play furiously on a work, as the angle of a half moon, in order to demolish and make a gap or breach in it.

In this, they obferve never to fire a fingle piece againft the top of the wall, but all towards the bottom, from three to fix feet from the ground; they also fire par camarade, all together, till they perceive the earth fall from behind the lining of the rampart.

BATTERING Pieces, or pieces of battery. See Cannon.

BATTEREROW, in Geography, lies on the west coast of Africa, 2 leagues from Disscore, and 5 leagues more from Cape Three points to the north of the eait.

BATTERSEA, a village and parish near London, in the county of Surry; where above 300 acres of land are occupied by the market gardeners, of whom there are about twenty, who rent from 5 or 6 to nearly 60 acres each. The gardens at Battersea pay seven shillings and sixpence per acre for tythes to their vicar. Lytton's Environ of London, vol. 1. p. 27.
